HEALTH SHRINES.

The idea that cures are inherent in certain localities is of hoar antiquity, and the pilgrimage which, we are informed, will start for Lourdes from Wimbledon next month is in a tradition dating from the beginning of the oldest civilisations known to us. The pilgrims will start encouraged by the belief that in 1922 two cases of Pott's disease and one of advanced tuberculosis were suddenly and radically cured at Lourdes. Such cures were necessarily "miraculous," for mere science or mere nature, though they may remove mountains on occasion, cannot suddenly arrest caries of the spine or restore the mischief done. A learned paper on the Cult of Asklepios and its rôle in the History of Medicine was read before the Third International Congress of the History of Medicine, by Dr. Alexander Cawadias, O.B.E., formerly chef de clinique of the Beaujon Hospital, Paris, and now senior physician and lecturer in clinical medicine at the Evangelismos Hospital, Athens. The paper has now been separately published as a pamphlet, in which Dr. A. Cawadias cites inscriptions discovered by his father, Dr. P. Cawadias, in the medical sanctuary at Epidaurus in 1881. "Some examples," writes Dr. Cawadias, "taken from the inscriptions discovered by my father in which are laid down the cures of Asklepios, will convince us that these cures were simple miracles such as are to-day the miracles of the Madonna of Lourdes or those of the Holy Virgin of Tenos in the Ægean." The inhabitants of the Ægean shores, when civilisation centred on those coasts, knew nothing of Pott's disease as a syndrome, but they believed that visits to particular shrines such as Epidaurus cured this and a number of other complicated conditions. "A woman is pregnant for five years," says the pamphlet, quoting the inscriptions. "After sleeping in the temple she awakes and is obliged to run rapidly out of the sanctuary because she felt that her pregnancy was coming to an end. She gave birth to a child which immediately after birth began to wash himself unaided, to walk and follow his mother." Again, a man with four fingers paralysed did not believe in the cures of Asklepios, but he consented to sleep in the Abaton, a building near the temple of Epidaurus specially dedicated to cures. While here he dreamt that he saw himself playing dice, and that the god rushed in and extended his fingers. A man, apparently blind of one eye, dreamt that he saw the god dropping something into the orbit. Both he and the man with a numbness of the fingers were thus miraculously cured. The dream and the vision of the god form part of the ritual of the cure in ancient times, just as among modern believers the cure has been preceded by an apparition either of a saint or a higher power. Among the Hindoos of the time of Père Dubois, for instance, a good-looking young priest invariably appeared in a dream in certain temples frequented by barren wives anxious to conceive and bear children. It would be unfair, however, to suggest that Lourdes and such shrines alone represent the survival of primitive faiths. The Continent, despite its rationalism, positively exudes belief in folk-medicine. No need for the French peasant—certainly in the Eastern provinces—to go to Lourdes to be cured of rheumatism in a vision. He can buy a cat-skin from among the pile in many a chemist's shop, and this will cure him if laid on the afflicted place, for it is still supposed to contain electricity. And, at any rate, as a grave person recently informed us, it keeps you warm. The established price of such a skin is 15 francs.

NEW MEDICAL EQUIPMENT IN THE UNITED STATES ARMY.

The Medical Corps of the U.S. Army has a Medical Field Service School, in association with which is the Medical Department Equipment Laboratory at Washington. Here was planned the U.S. first-aid packet (The Lancet, 1922, i., 960), and recently Major J. P. Fletcher, the Director, tells[1] us it has devised a battalion dispensary equipment to supply the needs of a battalion medical officer, particularly with regard to the requirements of the main dressing station. Experience having shown that 20 per cent. is the proportion of casualties to be expected, these have been averaged, and supply of dressings, &c., has been calculated thereon. The foundation of the equipment is four cases, measuring 31 in. by 19 in. by 15 in., marked M.D. 1, 2, or 3 (M.D. 1 is in duplicate). The cases have steel corners and are built up, not of three-ply wood merely, but of three-ply wood backed with steel, $\frac{1}{4}$ in. in all, a material which is thick, light, and strong, and easily got because used for trunk making in the United States. Each weighs

ARTIFICIAL HELIOTHERAPY.—Recently the Hull Corporation authorised the maternity and child welfare committee to establish an experimental sunshine clinic for the administration of artificial heliotherapy to ailing and rickety children under 10 years of age.

Messrs. W. Heffer and Sons, Ltd., announce the early appearance of Practical Physical and Colloid Chemistry for Students of Biology and Medicine, by Prof. Leonor Michaelis, of Berlin, translated from the second German edition by T. R. Parsons, M.A., B.Sc., demonstrator in physiology in the University of Cambridge.

THE Kent County Council, at their quarterly meeting, held on August 6th, decided unanimously to increase the salary of their county medical officer, Dr. Alfred Greenwood, from £1400 to £1600, without any application having been made by that officer.

THE annual report for 1923 of the Chief Medical Officer of the Ministry of Health, shortly to be issued to the public, is 211 pages in length, including four short appendices, and may be obtained either direct from H.M. Stationery Office or through any bookseller, price 3*s*.

COTTON-SPINNERS' CANCER.—Following on the ruling of Judge Mossop in the test case before the Ashton under-Lyne County Court (see THE LANCET, August 2nd p. 239), where compensation was awarded to an operative mule-spinner who had contracted epithelioma of the scrotum in the course of his employment, an Oldham mill company has been served with a claim for compensation under the Workmen's Insurance Act. The case is that of a cotton-spinner who has been dead for two years, and who ceased his connexion with spinning eight years before his death.

THE LATE DR. R. A. WILLIAMS.—Dr. Robert Arthur Williams, who died recently at his residence at Porthcawl, was one of the oldest medical practitioners in South Wales and was well-known throughout Glamorgan. A native of Carnarvon, he was 74 years of age, and had been in general practice for nearly 43 years, 28 of which were spent at Ogmore Vale. He will be remembered by his many friends and patients, who had for him a great admiration as one of the rescue party in the Park Slip Colliery explosion, which occurred some 30 years ago and in which he nearly lost his life. Dr. Williams, who was one of the senior magistrates of the county, was a graduate of Edinburgh University, having qualified M.B., C.M. in 1882. He leaves a widow, one son, and two daughters.

DONATIONS AND BEQUESTS.—Under the will of the late Alderman G. Macpherson, of Wolverhampton, the testator left, among other bequests, £250 to the Royal Orthopædic and Spinal Hospital, Birmingham; £250 to the Royal Orphanage, Wolverhampton; £250 to the Wolverhampton and Midland Counties Eye Infirmary; and £250 to the Wolverhampton and Staffordshire General Hospital. Failing certain family trusts, he left £5000 to the Royal Orthopædic and Spinal Hospital, Birmingham; £5000 to the Royal Orphanage, Wolverhampton; £5000 to the Wolverhampton and Midland Counties Eye Infirmary; £5000 to the Wolverhampton and Staffordshire General Hospital; and the ultimate residue to the British Red Cross Society and/or such other societies, hospitals or institutions as may have been founded or established for the relief, cure, care, maintenance or support of wounded and disabled or blinded soldiers and sailors.—By the will of the late Mrs. Mary Frances Thorne, of Dunconusg, Lossiemouth, N.B., and of Heckfield, Hants, the testatrix left £1000 to the London Hospital, Whitechapel, for the maintenance of the "Maggie's Bed," and £1000 to the Royal Free Hospital, Gray's Inn-road, for the maintenance of the "Augustus Thorne" Bed.—The late Mrs. Louisa Walker, of Leytonstone, Essex, left by will £500 each to the London Hospital and the Poplar Hospital for Accidents.—By will the late Mrs. Camilla Anna Olympia Bertie-Roberts, of Chelsea left, among other bequests, £2000 equally between the Chelsea Hospital for Women, the Victoria Hospital for Children, the West End Hospital for Nervous Diseases, the Ophthalmic Hospital, the Normal School of Music for the Blind, and the Seamen's Hospital, Greenwich, and £100 to the Home for Disabled Soldiers and Sailors as well as £50 to the Home for the Dying, Mare-street, Hackney.—Among other bequests, the late Mr. G. M. Henton, of Leicester, left by will £1000 to the Leicester Infirmary.—The late Mrs. Emma Hinchliffe, of Upper Norwood, bequeathed by will £2000 to the Hospital for Sick Children, Great Ormond-street, in memory of her husband, Walter Hinchliffe; £1000 each to the Sunshine House Blind Babies' Home, Chorley Wood, the Westminster Hospital, the Cancer Hospital, Fulham-road, the Home for Incurables, Streatham, and the Home for Incurables, Putney; and (after personal bequests) all other her property "to the hospitals named above, especially those for children."

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 18th.—11 A.M., Surgical Registrar: Surgical Wards. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

TUESDAY.—12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks Davis: Throat, Nose, and Ear Operations.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, August 18th, to SATURDAY, August 23rd.—THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. Mon., 10 A.M., Dr. Burrell: Demonstration of Cases illustrating Protein Tests and Treatment of Asthma. 12 noon, Dr. Beaumont: Demonstration of Cases. 2 P.M., Dr. Melville: Demonstration in X Ray Department. Tues., 10.30 A.M., Dr. Punch: Demonstration of Morbid Anatomy. 11.30 A.M., Dr. Davidson: Demonstration of Cases. Wed., 10.30 A.M., Mr. Tudor Edwards: Operations. 2 P.M., Dr. Gosse: Demonstration in Wards. Thurs., 10 A.M., Dr. Burrell: Artificial Pneumothorax and Thoracoscopy. 12 noon, Dr. Beaumont: Demonstration of Cases. Fri., 10 A.M., Dr. Davidson: Demonstration of Cases. 11 A.M., Dr. Nelson: Artificial Pneumothorax. 2 P.M., Mr. J. E. H. Roberts: Operations. Sat., 11 A.M., Dr. Batty Shaw: Demonstration of Cases.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E. Mon., 10 A.M., Mr. Broster: Cases illustrating General Surgery. 2 P.M., Mr. Nesfield: Conjunctivitis, Corneal Ulcer, Corneal Opacity. 4.30 P.M., Mr. Kenneth Lees: Demonstration on Mastoid Operation. Tues., 11 A.M., Mr. Kenneth Lees: A Practical Demonstration on Tonsillectomy. 2 P.M., Dr. King: Medical Cases. Wed., 10 A.M., Mr. Todd: Cases illustrating Orthopædic Principles. 2 P.M., Mr. Nesfield: Squint and its Treatment; Some Points in Refraction in Children; The Blindness of One Eye in Children. Thurs., 10 A.M., Dr. Winnicott: Medical Cases. 2 P.M., Mr. Whitchurch Howell: Demonstration of Surgical Cases, chiefly Orthopædic. Fri., 10 A.M., Mr. Broster: Cases illustrating General Surgery. 3.30 P.M., Mr. N. C. Lake: Surgical Treatment of Hypertrophic Stenosis. Sat., 10 A.M., Mr. Whitchurch Howell: Operations.

Appointments.

ADAM, J., M.B., C.M. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Handsworth District of the county of York.

DORWARD, W. F., M.B., Ch.B. St. And., Superintendent of the St. Luke's Hospital at Haifa under the Jerusalem and the East Mission.

MERCER, L. D., M.B., Ch.M. Sydney, F.R.C.S. Edin., Honorary Assistant Surgeon for Diseases of the Ear, Nose, and Throat, Salford Royal Hospital.

PLATT, H., M.D., M.S., F.R.C.S. Eng., Consulting Orthopædic Surgeon to the Lancashire Education Committee.

SMITH, N. ROSS, F.R.C.S. Eng., Resident Medical Officer to the Freemasons Hospital and Nursing Home, Chelsea.

Vacancies.

For further information refer to the advertisement columns.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each £200.

Brighton, New Sussex Hospital.—H.S. £50.

Bristol General Hospital.—Two H.P.s, two H.S.'s, Res. Obstet. O., and Cas. H.S. Each £80.

Bristol Royal Infirmary.—Cas. H.S., Obstet. and Ophth. H.S. Each £100. H.P.'s and H.S.'s and Asst. Obstet. H.S. Each £80. Also Dental H.S. £116.

Oliver-Sharpey Lectures.

Delivered before the Royal College of Physicians of London

By A. V. HILL, Sc.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON.

LECTURE II.*—THE RECOVERY PROCESS IN MAN.

Lactic Acid in Man.

It is a common observation that after exercise breathing is deep and rapid—that recovery is necessary. The same process must occur as in the isolated muscle, complicated in this case by the presence of the respiratory and circulatory mechanism. It can be shown that lactic acid occurs in human muscles as it occurs in isolated amphibian muscles. It had not been realised, however, till recently, how extensive are the changes connected with the lactic acid which is produced in the human body during exercise. When an athlete is running as fast as he can, about 3 g. of lactic acid per second are being liberated in his muscles! There are several signs of this lactic acid in the body. It occurs in the urine after prolonged hard exercise. In the blood of a resting man there is 0·01 to 0·02 per cent.; during and after severe exercise there may be as much as 0·20 per cent. This may be estimated directly by chemical analysis, or it may be inferred, as Barcroft did, from the change it produces in the oxygen dissociation curve. There is a very high respiratory quotient during, and especially just after, severe exercise; the lactic acid raises the hydrogen-ion concentration of tissues and blood; this stimulates the respiratory centre, with the result that CO_2 is eliminated by the lungs. In a later stage of recovery correspondingly the respiratory quotient falls to very low values as the lactic acid is removed. The chief sign, however, of the amount of lactic acid present in the body after exercise is the magnitude of the so-called oxygen debt. A muscle which has been active requires oxygen to carry out the combustions needed to provide the energy for the restoration process. The oxygen used in recovery is a measure of the magnitude of that process—that is, of the amount of lactic acid removed. Assuming an efficiency of recovery of 5·2 : 1, one litre of oxygen consumed after exercise is equivalent to 7 g. of lactic acid removed. The greatest oxygen debt hitherto recorded is one of nearly 19 litres, which corresponds to a concentration of lactic acid of not far from 0·35 per cent. in all the muscles of the subject; he was well-nigh exhausted.

Studies of Oxygen Intake.

The greater part of our knowledge of the events occurring in human muscular exercise has been arrived at by studies of the oxygen consumption. The measurement of oxygen intake is possible in many ways, two of which have been widely used in recent years. The first, which was employed by Benedict and Cathcart among others, involves the continuous circulation of oxygen in a closed system which includes the lungs of the subject, the CO_2 being absorbed and the diminution in volume owing to consumption of O_2 being recorded. The method is accurate but inadaptable; it is not capable of analysing the time course of the oxygen consumption when the latter is changing rapidly, as at the beginning and end of exercise. For such purposes the technique of the Douglas bag, in which the subject expires into a large bag carried on his back or in front of him, and the expired gases are analysed and their volume measured, is just as accurate as the other method and is capable of following very rapid changes. It is possible to use this method when walking, running, riding a bicycle, even swimming, and to plot the time course of the oxygen consumption in intervals as short as half a minute. Under certain circumstances even quarter minute intervals may be employed.

The "Steady State."

In my previous lecture I spoke about the steady state of an isolated muscle contracting in an atmosphere of oxygen; in such a muscle there is a balance between breakdown and recovery. Remember that the recovery process is more rapid when the total amount of breakdown causing it is greater; lactic acid is a sensitive governor of oxygen usage. Hence, if we start with a given rate of breakdown, as when a man suddenly begins to run at a given speed, the rate of recovery, starting from zero, has to work up gradually until it balances the rate of breakdown. It is necessary, moreover, in the intact animal for the circulation and respiration to work up also. In a subject starting to run, having been previously at rest, the oxygen intake rises to its full steady value in a period of about two to two and a half minutes (see Fig. 3). If the running be continued at a constant speed the oxygen intake also remains constant thereafter—or almost constant—till the end of the exercise (Fig. 3, Curve I.); the subject is in what we may call a "steady state." This state corresponds to a constant concentration of lactic acid in the muscles, constant owing to a balance between formation and removal. As the exercise, however, is continued, the lactic acid present in the active muscles gradually passes, by diffusion, into the blood and thence to other parts of the body. This is probably one explanation of the fatigue resulting from long-continued, moderate exercise, a matter now being more fully studied by Lupton and Long. The oxidative removal of the lactic acid formed in one muscle may in this manner occur in other distant muscles by its passage, via the blood, from the one to the other. As Barr in New York has found, the venous blood from a resting muscle, during the vigorous activity of others, may contain *less* lactic acid than the arterial blood coming to it. Indeed, in this sense it is possible to recover in one's arms from exercise taken in one's legs! This may be an important factor in recovery from vigorous exercise taken by small portions of the muscular system; it cannot have much effect in severe general exercise.

It is to be noted that an apparent "steady state" may occur, during muscular exercise, in which the oxygen intake is constant, which is not, however, really "steady" at all; there is a continual onset of fatigue. The oxygen intake may attain its maximum (Fig. 3, Curve II.) and remain constant merely because it cannot go any higher (e.g., to Curve III.) owing to the limitations of the circulatory and respiratory system. Such a condition causes an accumulation of lactic acid in the muscle and can end only in complete exhaustion.

Recovery.

When the exercise terminates the lactic acid in the muscles must be removed and oxygen must be taken in to provide the necessary energy. The lag in the oxygen intake at the beginning of exercise, during which the lactic acid was concentrating, must be compensated by an extra intake afterwards when it is diminishing again. After a short bout of moderate exercise (Curve I.) the oxygen intake falls in a period of five to ten minutes to its resting value. After severe or prolonged exercise (Curve III.) it may be an hour before the oxygen intake is normal again. The total amount of oxygen used in the recovery process may be measured by collecting the whole of the expired gases over any desired interval, by an estimation of the total oxygen used in that interval, and subtraction of the amount of oxygen which the subject would have used had he remained throughout at rest.

"Oxygen Requirement."

It is desirable here to introduce a new term—namely, the "oxygen requirement" of exercise. If the exercise be very mild (Fig. 4), then the oxygen requirement may be met by the actual oxygen

---

[1] Lecture I. appeared in The Lancet of August 16th.

39 lb. The two M.D. 1 cases carry dressings; they stand on their ends and open like a wardrobe. In the lid is a flap-table which rises when the lid is opened to a right angle, and articulates with the rest of the chest to form a table for instruments, &c., and there is a fitting to hold the handles of a stretcher on the side of the chest. The chests M.D. 2 and 3 are mére shells, their contents being carried in trays, so planned that they can be taken out and built up into something like a dinner wagon, when all their stores are available without further unpacking. The whole equipment has been very carefully thought out. M.D. 2 is "the drug trunk," and M.D. 3 "the kitchen trunk," with a flashlight, a gasoline stove, a six-quart kettle, tea, coffee, and milk to provide the wounded with hot drinks; even cigarettes are not forgotten. In addition, there is a "lantern crate," with paraffin, three hurricane lamps, and three spare glasses. Also there is a small tent with pole sections to shelter one or two stretcher cases under operation. A bag of splints, a bag for sterilising water, 12 stretchers, 36 blankets, shovel, pick, &c., complete this large supply. We would point out, however, that Major Fletcher's paper must be read in the original, for without the illustrations it is impossible to appreciate the ingenuity of the apparatus. Further, we commend a system which allows the officer chiefly responsible for a novel equipment, as this is, to explain it to the Service before issue, thus winning for it in advance interest and perhaps approval, and side-tracking ill-informed criticism.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editor of The Lancet.

Sir,—Will you allow us to make a very urgent appeal for funds to send working girls and women away for a short holiday? Many of those who are hoping to go during the next few weeks have never slept out of London for a single night. They have been saving up for months to get this unique privilege, and are even now counting the days in hot workshops and dusty factories, till they can have if only one week of freedom and fresh air. The large amount of unemployment which still continues among men has made the women and girls in many cases the sole support of their families. It is obvious that these cannot pay much towards their holidays; obvious, too, that young people living in narrow streets and overcrowded rooms may be permanently injured in health if no change is possible.

In weather such as this, who can happily arrange or take a holiday without doing something to enable those less fortunate to have—for even one week—the good food and rest and refreshment that may set them up for the long months of the winter's work?

Subscriptions and donations will be thankfully received by the Chairman of the Executive Committee, Mr. J. F. Green, or Miss Canney, 75, Lamb's Conduit-street, W.C. 1.

Yours faithfully,
(Signed) Alberta Sandwich, Mary St. Helier, J.P., L.C.C.
A. F. London, J. A. Hertz, Chief Rabbi.
Mary Scharlieb, Robert F. Horton,
Louise Creighton, Frank Lloyd.

August 11th, 1924.

MEDICAL ATTENDANCE IN STREET ACCIDENTS.

The Bolton watch committee has received a letter from the branch secretary of the British Medical Association, Lancashire and Cheshire Branch, stating that the branch had been requested by the Chief Constable of Lancashire to lay down a scale of fees for attendance on cases of accidents or sudden illness in the street when a medical man is summoned, and that the following fees were accepted by the Chief Constable of Lancashire as being suitable—viz., between 8 A.M. and 8 P.M., 7*s.* 6*d.* per visit; between 9 P.M. and 8 A.M., 15*s.* per visit, with mileage of 1*s.* per mile beyond one mile from the residence or surgery of the doctor called on by the police to give medical and surgical aid; and asking this committee to adopt a similar scale of fees. The Chief Constable recommended that the scale should be adopted and the committee agreed.

AN AID IN DEFÆCATION.

The ordinary closet seat does not permit the squatting position to be used in the act of defæcation, though there are many sound reasons why this position, which is naturally assumed by primitive peoples and children, is to be commended. For the last 20 years improved closet seats have been exhibited at medical gatherings, see, for instance, The Lancet, 1905, ii., 167. We have now received from the Proper Adjustable Foot Rest Company, 36, Northgate, Newark-on-Trent, Notts, a description of an adjustable foot-rest the use of which ensures the correct squatting position on the w.c. seat. It can be used with any w.c. pan, is adjustable for tall or short people, and is readily affixed to wood, tile, or concrete flooring. The price is 45*s.*

GRATUITOUS MEDICAL ATTENDANCE.

To the Editor of The Lancet.

Sir,—Among the unwritten laws of medical ethics there appears to be fluctuations, yet, I suppose, there are certain fixed or semi-fixed ideas which are held more or less in common.

I am writing to ascertain the general view of the medical profession with regard to non-medical persons from whom fees should not be accepted. Naturally "hawks dinna pyke oot hawks e'en," and the doctor goes scot-free. His wife also is exempt. On these points I have no doubt all are in agreement. What I should like to know is how far the list extends. I venture to schedule the following:—Doctors' widows; doctors' children, while dependent; nurses and medical students.

In old days I believe clergymen were placed on the free list, and qualified dentists also. Probably this is still general. Would one now include those whose activities are placed at the profession's disposal—e.g., chemists?

I think the point may not be without interest because practice in these matters does not appear to be uniform.

I am, Sir, yours faithfully,
August 9th, 1924. Inquirer.

*** As the medical profession has become more subdivided, and as the groups directly ancillary to medicine have become more numerous, applicability of general rules has been found in practice impossible. No doctor charges a doctor, but even here there may be exceptions by mutual agreement, the reasons for which will occur to everyone. Again, if the widow of a doctor can pay easily for medical attendance, she does not, as a rule, demand gratuitous services from medical men who are strangers; while no practitioner, previously in relations with her husband, allows her to pay except as the result of conversation on the subject. With regard to medical students, their care naturally devolves without payment of fees on those who have charge of their studies, though it is easy to see that here particular circumstances might dictate quite naturally the offer and the acceptance of fees. Nurses always obtain medical advice and treatment from those with whom they work professionally. But the qualified dentist is in rather a different case and is usually dealt with in accordance with particular circumstances; no general law can possibly meet those circumstances, but mutual arrangements that are fair and that preserve professional cordiality can usually be arrived at. The custom of attendance upon the clergy has for many years followed the individual inclination of practitioners, but the sympathy of the medical profession for their ill-paid clerical colleagues has always been practically manifested, and is so to-day.—Ed. L.

URGENT TELEPHONE CALLS.

To the Editor of The Lancet.

Sir,—In The Lancet of August 9th you quote from Dr. Waldo's remarks concerning the ignorance of the public about all matters connected with fires, especially his observation that: "Not uncommonly, again, on the breaking out of a fire, persons on using the 'phone merely say—Fire! and, without waiting to give their address, replace the receiver and await the arrival of the fire brigade, which, of course, never comes." But I would point out the instruction in the London Telephone Directory is ambiguous in this respect, as will be seen by the extract which follows:

> Emergency Services. (Fire, Ambulance, Police.)
>
> If in case of emergency the Fire, Ambulance, or Police service is required, all that is necessary is to answer the telephonist's query "Number, please?" with the word, "Fire," "Ambulance," or "Police," as the case may be. *Do not give number.* (See instructional headlines.)

I suppose this means: "Do not stop to give the number of any fire station, but give your own name and address and number"; but it could be read: "Do not give any number at all."

I am, Sir, yours faithfully,
F. W. W.

*** In a letter just issued to the press by the Chairman of the Metropolitan Boroughs' Traffic Subcommittee, it is stated that in case of accident the telephone exchange should be asked for "ambulance"; no number is required and no charge is made for the call, whether it is made from a public call office or from a private telephone. As soon as the caller gets through to the headquarters of the Ambulance Service, *particulars as to the locality of the accident or illness should be made together with the name of the caller.* To enable premises upon which a telephone is available to be readily identified, the London County Council have prepared indicating tablets containing the letter "A" which will be placed outside premises, from which, by the courtesy of the occupants, an ambulance may be summoned. Telephone subscribers who are willing to assist in this direction are asked to send their telephone numbers and addresses to the Officer in Charge of the Service, 94, Southwark Bridge-road, S.E. 1.—Ed. L.

Oliver-Sharpey Lectures.

Delivered before the Royal College of Physicians of London

BY A. V. HILL, Sc.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON.

LECTURE II.*—THE RECOVERY PROCESS IN MAN.

LACTIC ACID IN MAN.

IT is a common observation that after exercise breathing is deep and rapid—that recovery is necessary. The same process must occur as in the isolated muscle, complicated in this case by the presence of the respiratory and circulatory mechanism. It can be shown that lactic acid occurs in human muscles as it occurs in isolated amphibian muscles. It had not been realised, however, till recently, how extensive are the changes connected with the lactic acid which is produced in the human body during exercise. When an athlete is running as fast as he can, about 3 g. of lactic acid per second are being liberated in his muscles! There are several signs of this lactic acid in the body. It occurs in the urine after prolonged hard exercise. In the blood of a resting man there is 0·01 to 0·02 per cent.; during and after severe exercise there may be as much as 0·20 per cent. This may be estimated directly by chemical analysis, or it may be inferred, as Barcroft did, from the change it produces in the oxygen dissociation curve. There is a very high respiratory quotient during, and especially just after, severe exercise; the lactic acid raises the hydrogen-ion concentration of tissues and blood; this stimulates the respiratory centre, with the result that CO_2 is eliminated by the lungs. In a later stage of recovery correspondingly the respiratory quotient falls to very low values as the lactic acid is removed. The chief sign, however, of the amount of lactic acid present in the body after exercise is the magnitude of the so-called oxygen debt. A muscle which has been active requires oxygen to carry out the combustions needed to provide the energy for the restoration process. The oxygen used in recovery is a measure of the magnitude of that process—that is, of the amount of lactic acid removed. Assuming an efficiency of recovery of 5·2 : 1, one litre of oxygen consumed after exercise is equivalent to 7 g. of lactic acid removed. The greatest oxygen debt hitherto recorded is one of nearly 19 litres, which corresponds to a concentration of lactic acid of not far from 0·35 per cent. in all the muscles of the subject; he was well-nigh exhausted.

STUDIES OF OXYGEN INTAKE.

The greater part of our knowledge of the events occurring in human muscular exercise has been arrived at by studies of the oxygen consumption. The measurement of oxygen intake is possible in many ways, two of which have been widely used in recent years. The first, which was employed by Benedict and Cathcart among others, involves the continuous circulation of oxygen in a closed system which includes the lungs of the subject, the CO_2 being absorbed and the diminution in volume owing to consumption of O_2 being recorded. The method is accurate but inadaptable; it is not capable of analysing the time course of the oxygen consumption when the latter is changing rapidly, as at the beginning and end of exercise. For such purposes the technique of the Douglas bag, in which the subject expires into a large bag carried on his back or in front of him, and the expired gases are analysed and their volume measured, is just as accurate as the other method and is capable of following very rapid changes. It is possible to use this method when walking, running, riding a bicycle, even swimming, and to plot the time course of the oxygen consumption in intervals as short as half a minute. Under certain circumstances even quarter minute intervals may be employed.

THE "STEADY STATE."

In my previous lecture I spoke about the steady state of an isolated muscle contracting in an atmosphere of oxygen; in such a muscle there is a balance between breakdown and recovery. Remember that the recovery process is more rapid when the total amount of breakdown causing it is greater; lactic acid is a sensitive governor of oxygen usage. Hence, if we start with a given rate of breakdown, as when a man suddenly begins to run at a given speed, the rate of recovery, starting from zero, has to work up gradually until it balances the rate of breakdown. It is necessary, moreover, in the intact animal for the circulation and respiration to work up also. In a subject starting to run, having been previously at rest, the oxygen intake rises to its full steady value in a period of about two to two and a half minutes (see Fig. 3). If the running be continued at a constant speed the oxygen intake also remains constant thereafter—or almost constant—till the end of the exercise (Fig. 3, Curve I.); the subject is in what we may call a "steady state." This state corresponds to a constant concentration of lactic acid in the muscles, constant owing to a balance between formation and removal. As the exercise, however, is continued, the lactic acid present in the active muscles gradually passes, by diffusion, into the blood and thence to other parts of the body. This is probably one explanation of the fatigue resulting from long-continued, moderate exercise, a matter now being more fully studied by Lupton and Long. The oxidative removal of the lactic acid formed in one muscle may in this manner occur in other distant muscles by its passage, via the blood, from the one to the other. As Barr in New York has found, the venous blood from a resting muscle, during the vigorous activity of others, may contain *less* lactic acid than the arterial blood coming to it. Indeed, in this sense it is possible to recover in one's arms from exercise taken in one's legs! This may be an important factor in recovery from vigorous exercise taken by small portions of the muscular system; it cannot have much effect in severe general exercise.

It is to be noted that an apparent "steady state" may occur, during muscular exercise, in which the oxygen intake is constant, which is not, however, really "steady" at all; there is a continual onset of fatigue. The oxygen intake may attain its maximum (Fig. 3, Curve II.) and remain constant merely because it cannot go any higher (e.g., to Curve III.) owing to the limitations of the circulatory and respiratory system. Such a condition causes an accumulation of lactic acid in the muscle and can end only in complete exhaustion.

RECOVERY.

When the exercise terminates the lactic acid in the muscles must be removed and oxygen must be taken in to provide the necessary energy. The lag in the oxygen intake at the beginning of exercise, during which the lactic acid was concentrating, must be compensated by an extra intake afterwards when it is diminishing again. After a short bout of moderate exercise (Curve I.) the oxygen intake falls in a period of five to ten minutes to its resting value. After severe or prolonged exercise (Curve III.) it may be an hour before the oxygen intake is normal again. The total amount of oxygen used in the recovery process may be measured by collecting the whole of the expired gases over any desired interval, by an estimation of the total oxygen used in that interval, and subtraction of the amount of oxygen which the subject would have used had he remained throughout at rest.

"OXYGEN REQUIREMENT."

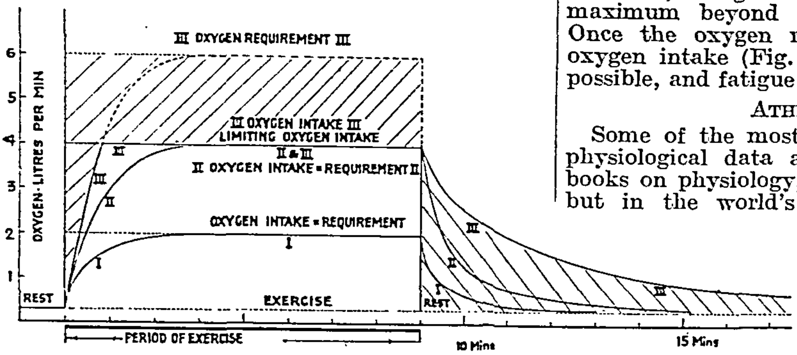
It is desirable here to introduce a new term—namely, the "oxygen requirement" of exercise. If the exercise be very mild (Fig. 4), then the oxygen requirement may be met by the actual oxygen

---

[1] Lecture I. appeared in THE LANCET of August 16th.

intake once the steady state has been attained. If, however, the exercise be severe the oxygen requirement cannot be met, even when the heart and lungs have attained their maximum activity; if the exercise be persisted in, the body necessarily incurs what we may call an oxygen debt. *Were it* not for the fact that the body is able to obtain its energy in this way, by using its necessary oxygen afterwards, severe exercise would be impossible in man. We should never be able to run upstairs, or to run on the flat at more than eight or nine miles an hour. We can do so only because Nature has provided us with an arrangement, like an accumulator which can be run down at a very high rate, as in starting a car, and then must be recharged slowly afterwards.

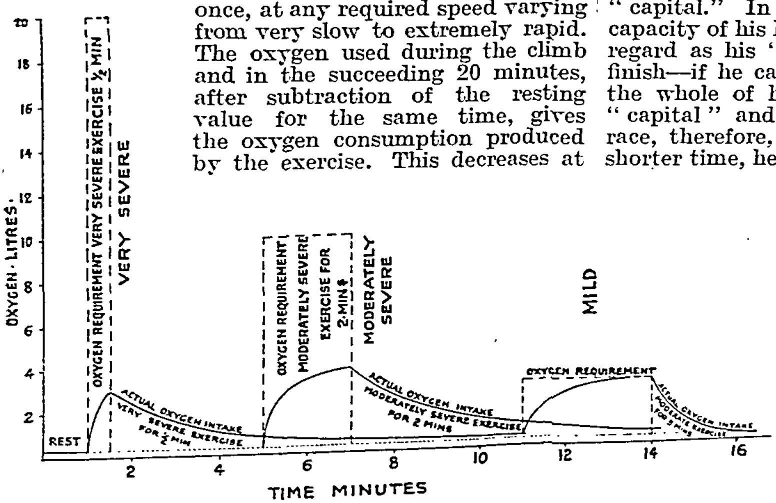
FIG. 3.



The oxygen requirement of a given type of exercise, or of a given isolated movement or series of movements, can always be measured. The oxygen requirement may be much higher than any possible oxygen intake. If, however, the movement be carried out only for a short time, and the total oxygen used *during it, and in recovery from it*, be measured, then the total oxygen so found is the requirement of that piece of exercise. In this way it is possible to study the energy requirement of even the most violent and discontinuous movements. To take an example, Lupton has measured the maximum efficiency of the process of climbing a staircase; not for the intrinsic interest of that process, but in an endeavour to show that there exists, for many muscular movements, a certain optimum rate. The subject ascends the staircase once, at any required speed varying from very slow to extremely rapid. The oxygen used during the climb and in the succeeding 20 minutes, after subtraction of the resting value for the same time, gives the oxygen consumption produced by the exercise. This decreases at first as the speed is increased, and then increases again, showing that there is indeed an optimum speed.

This existence of an optimum speed does not occur in all types of exercise. In running the oxygen *requirement* increases continuously as the speed increases, though the actual oxygen *intake* reaches a maximum beyond which no effort can drive it. Once the oxygen requirement is larger than the oxygen intake (Fig. 3), a steady state is no longer possible, and fatigue ensues more or less rapidly.

FIG. 4.



Example of "oxygen requirement." Rest 200 c.cm./min.; ½ min. exercise; total oxygen during exercise and in subsequent 14½ min. (recovery assumed complete) = 10 litres. Oxygen consumption due to the exercise 10 − 15 × 0·2 = 7 litres = 14 litres per min. requirement.

Example of "oxygen debt." Rest 250 c.cm./min.; exercise; total oxygen in 32 min. following exercise = 18 litres; subtract resting consumption 32 min. = 0·25 × 32 = 8 litres. "Oxygen debt" = 18 − 8 = 10 litres.

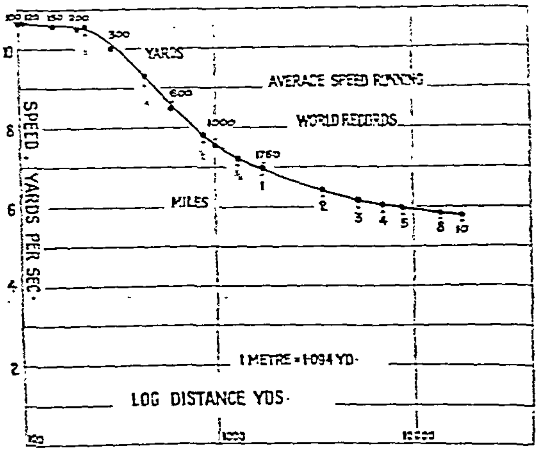
ATHLETIC RECORDS.

Some of the most accurate, the most consistent, physiological data available are contained, not in books on physiology, not even in books on medicine, but in the world's records for running different horizontal distances. If one plots the average speed at which the record was made, against the length of the race (compressed in some manner—as by taking its logarithm—to bring all the points on to the same diagram), then a curve (Fig. 5) of almost perfect smoothness is *obtained, in which a few points only lie just below* the curve. These latter are for the races in which athletes have not been so concerned to break the record as in the rest. The relation shown in the curve may be accepted practically as a natural constant for the human race; it would require almost a superhuman effort to change one of the points by 2 per cent.; and it is interesting to consider what determines the shape of this relation. At very short distances the speed is constant; it is the maximum which a man can attain, though it falls off a little as the accumulation of lactic acid in the muscles affects their speed of relaxation. At very long distances the speed again tends to become constant, practically a steady state to be attained. It is determined by the maximum amount of oxygen which the athlete can take in, to provide his muscles with their necessary energy, and the economy with which he uses it. Speed at intermediate distances is determined, partly by the maximum oxygen debt which the body can incur, partly by its maximum oxygen intake. We assume, of course, that we are dealing with a man in perfect condition, highly trained to carry out his movements in the most economical manner possible, ready and willing in a race to exhaust himself completely. In the magnitude of the oxygen debt, that is in the concentration of lactic acid which his muscles can tolerate, we have what we may regard as a man's "capital." In his oxygen intake, determined by the capacity of his heart and lungs, we have what we may regard as his "income." In a race an athlete will finish—if he can, if the race be not too short—with the whole of his reserves gone, having spent both "capital" and "income" completely. In a short race, therefore, he can spread his "capital" over a shorter time, he can expend energy more rapidly than he can in a long one; the form of the curve is determined mainly by these factors.

"OXYGEN DEBT."

Recently we have made a number of estimations of "oxygen debt." The most striking are those (*a*) in which 23 seconds of exercise led to a debt of 8·7 litres, (*b*) running for 33 minutes at a medium speed only of 7·9 litres, and (*c*) "standing running" with extreme violence for 4 minutes of 18·7 litres. The larger values mean enormous amounts of lactic acid accumulated in the body; how can this acid be tolerated? Inside the muscle are three alkalies capable of neutralising the acid, and the hydrogen-ion concentration in the active muscle does not rise very far so long as the amount of these alkalies is adequate. It would seem probable that the limit to which it is possible to press a muscle is determined by the amount of alkali within it capable of neutralising the acid product of its activity.

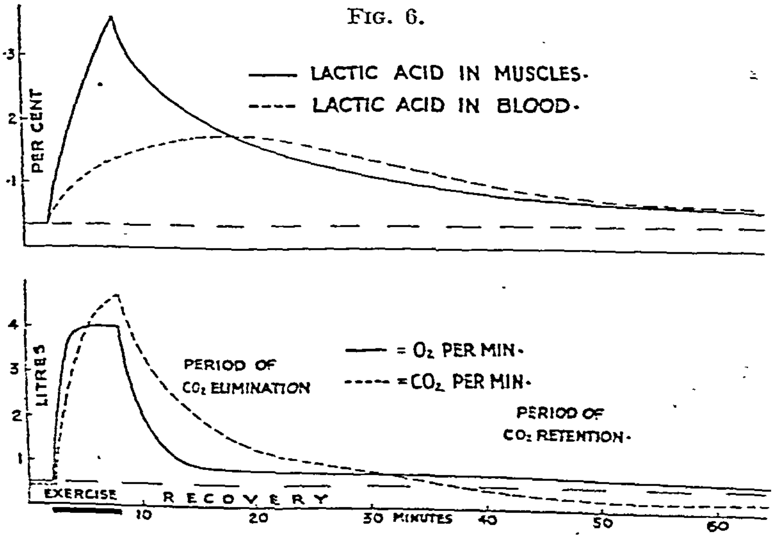
FIG. 5.



CO₂ ELIMINATION AND RETENTION.

This sudden production of acid, as pointed out above, is the explanation of the large amounts of CO_2 that come off during the exercise (Fig. 6, lower half). When the lactic acid is removed in recovery, the same quantity of CO_2 must be retained as was originally eliminated; sodium lactate must become sodium bicarbonate again. Consequently, we find very low respiratory quotients in the later stages of recovery. The CO_2 retained is a measure of the lactic acid got rid of. The oxygen used in recovery is a measure of the carbohydrate (or lactic acid) oxidised. The comparison of the two enables us to determine in man the "efficiency" of recovery. Again, we find that at most a small fraction of the lactic acid has been oxidised, the value determined for the "efficiency" of recovery is almost identical with that found in the case of isolated frog's muscle; a sufficient reward for the faith that Nature is consistent.

FIG. 6.



Direct Measurement of Lactic Acid.

During and after exercise lactic acid occurs in the blood; during the steady state of continued exercise this lactic acid accumulates to a constant concentration characteristic of the violence of the exercise. In my last lecture I showed that the speed of the recovery process depends upon the magnitude of the breakdown from which recovery is necessary. The rate of recovery, given an adequate supply of oxygen, is proportional roughly to the square of the concentration of lactic acid in the active muscle. The lactic acid is a sensitive governor of oxidation. If we regard the resting oxygen consumption of man as being due to recovery from very small amounts of exercise, slight bodily movements, movements of heart and lungs, muscular tone, then for four times the oxygen consumption, such as occurs in a steady state of ordinary walking, we should expect not four times the lactic acid concentration in the blood, but only twice; for 16 times the oxygen consumption—the limit approached during hard exercise—we should expect not 16 times, but four times the lactic acid concentration in the blood. Recent experiments by Long, still only preliminary, tend to some degree to confirm this expectation. It will be a very fortunate thing for the body if, when we take 16 times as much exercise, the lactic acid concentration in our blood only rises four times; it would have been very awkward had it been the other way round! It would seem almost a provision of Nature, an adaptation to a requirement, only that it is difficult to conceive how even evolution could have evaded the laws governing bi-molecular reactions. Perhaps it merely took advantage of one which happened to be available. *The fact, in any case, is an* interesting example of the application to man of one of the by-products of experiments first performed on frogs.

The lactic acid, however, is more interesting when we are not dealing with the steady state. After very severe exercise the lactic acid in the muscles cannot fall very rapidly owing to the inadequacy of the oxygen supply. *It diffuses out, therefore, into the blood and* all round the body. It reaches its maximum in the blood some ten minutes after it has attained its maximum in the muscles (Fig. 6, upper half). Hence the maximum in the blood is lower than in the muscles. At the particular moment, however, when it is at its maximum in the blood, we may be sure that it is the same in the muscles; equally it is certain to be the same in both at the end of recovery, when both are becoming constant. It is possible, therefore, by a direct analysis of lactic acid in the blood to ascertain the concentration in the muscles at two moments: (1) about ten minutes after exercise, and (2) towards the end of recovery. By such direct analyses it is possible to determine directly—if somewhat roughly—the amount of lactic acid which has disappeared in the recovery process. This may be compared, as in the case of the lactic acid calculated from the CO_2 retention, with the oxygen used in that removal, and it is found, as in the frog's isolated muscle, that the acid is not oxidised; only about one-sixth of the oxygen is used which would be required were all the lactic acid broken down to CO_2 and water. The same ratio for the "efficiency" of recovery is attained in man as in the isolated muscle.

FACTORS AFFECTING SPEED OF RECOVERY.

The speed of the recovery process depends in a healthy man on the oxygen supplied to the active muscles. This is limited by two factors: first, the total oxygen that can be taken through the lungs into the blood and circulated by the heart; second, the local circulation to the part involved. Many observations have been made of the oxygen intake of a man undergoing various forms of severe muscular exercise. The highest value recorded while breathing air is 4·2 litres per minute; breathing 50 per cent. oxygen, very nearly six litres has been reached. The only possible reason why more oxygen can be taken in, when breathing oxygen, is that the blood is not completely saturated during very severe exercise when breathing air; the greater saturation, however, of the coronary blood, when breathing oxygen, may then result in greater cardiac activity. The magnitude of the oxygen intake is determined mainly by the capacity of the heart, and I give later a calculation showing what this number means in heart output. The other factor determining the speed of the recovery process is the local supply of blood to the muscles actually involved in the work. Lindhard showed that in such exercise as holding the body with arms bent, on rings in a gymnasium, the blood-supply to the active muscles of the arm is almost completely cut off. The whole of the oxygen required had to be used after the exertion was over. In running the supply of blood to the active muscles is particularly easy, as they are never rigid and their movements are rapid. In rowing the supply of blood to the muscles must be much more difficult; the muscles are rigid for longer periods, and their movements are relatively slow; they exert less pumping action on the veins; consequently rowing places a greater strain on the heart.

Heart Output from Oxygen Intake.

The values of the oxygen intake during severe exercise allow a striking—if approximate—calculation of the output of the heart. Assuming, as was the case in the subject who consumed 5·9 litres of oxygen per minute, an oxygen capacity of 21 c.cm. per 100 c.cm. of blood, and an average utilisation coefficient of 75 per cent. (a value as high as has ever been recorded), then the actual oxygen taken in must have required 37·5 litres of blood per minute to carry it. This amount of blood has been ejected from the heart twice, from the right side once, and from the left side once; altogether, therefore, 75 litres of blood—about 17 gallons, about 120 times the heart's own volume—have been pumped out in every minute. Even assuming a utilisation coefficient of 100 per cent., 56 litres (12½ gallons) of blood must have been pumped together from the two sides of the heart. Compare these volumes with the amount of water which a bath tap can pour out in a minute, even when turned full on! In such exercise the heart-rate—recorded with a string-galvanometer—is about 180, which means that each side of the heart ejects some 200 c.cm. per beat. There is no possible flaw in the argument or calculation, otherwise it would be difficult to believe the conclusion. It is little wonder that the heart sometimes cannot stand the strain.

Energy Requirement of Heart.

It is possible, by an approximate calculation, to determine the oxygen consumption of the heart during such exercise. The calculated output of blood, multiplied by the blood pressure, gives us the work done; assuming an efficiency of 20 per cent., which is a high value under such conditions, the total energy used by the heart can be calculated. The provision of this energy requires the consumption of oxygen, and it would appear that the oxygen requirement of the heart during such exercise as that described above is about 300 c.cm. per minute—about half its own volume. Assuming a utilisation coefficient of 75 per cent. and an oxygen capacity as before, this requires two litres of blood to pass through the coronary vessels of the heart per minute. This volume of oxygen, actually used by the heart, is equal to that *required but never obtained* by voluntary muscle during the most violent exercise. The muscle has to stop within a minute, owing to oxygen-want; the heart, however, owing to its better oxygen-supply, when the coronary circulation is efficient, is able to keep up an output of this order for long periods.

Other Factors in Recovery.

The recovery process depends also on other factors. In my last lecture I showed how in the isolated muscle it depends on the hydrogen-ion concentration. Deep breathing, therefore, sweeping away the CO_2 and keeping the body alkaline, may be essential to the quickness of the recovery process. It must depend also upon the presence of oxidative catalysts. Recent work by Hopkins has shown the presence in tissues of a di-sulphide compound, glutathione, which acts practically as an oxidative catalyst. The discovery of similar substances has been made independently by Meyerhof. I need not discuss the mechanism of glutathione now, otherwise than to say that in its di-sulphide form it seems to act as a hydrogen acceptor and so to liberate oxygen for the oxidation of something else, and then itself to be oxidised, by molecular oxygen or otherwise, to its original di-sulphide form.

$$-S-S- + H_2O \longrightarrow -S-H + H-S- + O$$
$$-S-H + H-S- + \tfrac{1}{2}O_2 \longrightarrow -S-S- + H_2O.$$

Recent experiments by Hartree have suggested that an isolated muscle left in Ringer's solution has its speed of recovery diminished; this may be a time effect, but it is possibly due to the washing away of oxidative catalysts from the muscle by the Ringer's solution surrounding it. Clearly the experiment must be tried on muscles carefully perfused before use. It is likely, in any case, that the oxidising faculty of tissues will vary from individual to individual. It may be, therefore, that important divergencies from the normal will be found in persons suffering from various forms of dyspnœa, in respect of their oxidative metabolic power. Possibly athletes, and people accustomed to heavy work, will develop this side of their metabolic activities. Recent work by Miss Robinson in Hopkins's laboratory has shown that hæmoglobin has a very distinct catalysing power in the oxidation of unsaturated fats. The dyspnœa so often associated with anæmia may in some cases be due to the absence not only of an adequate oxygen-supply, but of an adequate amount of some oxidising catalyst. Recent work by Warburg and his colleagues has shown that many forms of biological oxidation probably occur as surface phenomena, catalysed by iron atoms embedded in the surface; the absence of the iron, or its removal from activity by physical or chemical means, will hinder or prevent oxidation, as also will displacement of the oxidisable bodies, by narcotics or other substances, from the active surfaces where oxidation goes on. Imperfect metabolism of iron, excretion of it, its combination with abnormal metabolites, the displacement of the bodies to be oxidised away from the oxidising surfaces might all lead, therefore, to an imperfect and slow recovery from exertion, to dyspnœa associated with exercise.

APPLICATIONS.

All of us can suffer from dyspnœa and all of us can exhaust ourselves very rapidly; the finest athlete in the world may be almost incapable of movement within 60 seconds from the beginning of a race. The same degree, however, of exhaustion may be produced by a much lower level of exercise, no more rapidly but just as effectively, in a person of lower oxidative faculty or with poorer buffers in his tissue. When I was lecturing recently in Holland on this subject it was remarked, after one of my lectures, that it was typical of an Englishman, when he had found an interesting bit of physiology, immediately to want to apply it to sport. Perhaps some of you will sympathise with the motive—there are worse ones—even if it be true. There is a better motive, however; athletes and healthy men give us the cleanest experiments. If one took a patient from the hospital and made him work till he could barely move, one could never be sure (*a*) that he had really driven himself to his limit—it requires an athlete to know how to exhaust himself; (*b*) that one would not kill him; and (*c*) what the cause of his stopping was. With young athletes one may be sure—if one knows one's men—that they really have gone "all out," moderately certain of not killing them, and practically certain that their stoppage is due to oxygen-want and to lactic acid in their muscles. Quantitatively the phenomena of exhaustion may be widely different, qualitatively they are the same, in your athlete, in your normal man, in your dyspnœic patient. You can only *observe* your patient, but you can *experiment* with your athlete; you can "try out" on him the facts and theories you have reached with frogs. There I must leave it, and be grateful if the young athletes in their turn can suggest further experiments on frogs. I should be afraid to try such experiments as I have described on your patients, and I do not for a moment suppose that they, or you, would let me. The fact, however, that you have done me the honour to invite me to give these lectures is a sign, I am happy to think, that you believe in some future application, to your own urgent problems, of the study of the recovery process in normal man. Even such experiments as these may lead, in the end, to the alleviation of human suffering. After all, it is a much longer trail from a small portion of a frog to a young athlete, than it is from him to a patient in a hospital. Faith in the consistency of nature has been rewarded on the one trail; it cannot fail to be rewarded on the other.

CHLORIDE METABOLISM IN RONTGEN RAY THERAPY.

By A. T. CAMERON, B.Sc., F.I.C., F.R.S.C.,
PROFESSOR OF BIOCHEMISTRY, FACULTY OF MEDICINE, UNIVERSITY OF MANITOBA; ASSOCIATE IN BIOCHEMISTRY, WINNIPEG GENERAL HOSPITAL;

AND

J. C. McMILLAN, M.D.MANIT., F.A.C.P.,
LECTURER IN RADIOLOGY, DEPARTMENT OF INTERNAL MEDICINE, UNIVERSITY OF MANITOBA; MEDICAL DIRECTOR, X RAY DEPARTMENT, WINNIPEG GENERAL HOSPITAL.

Dodds and Webster [1] have recently summarised the literature of radiation sickness in THE LANCET, and Schmitz [2] at the same time published a similar summary in *Radiology*. The three cases of sickness examined by the first-named authors showed no metabolic disturbance. Schmitz's summary is inconclusive as to the cause of the sickness. Dodds and Webster do not appear to have seen a paper by Cori and Pucher [3] which appeared in September last, and in which the results appear to indicate that Rontgen radiation produces a definite chloride retention, more marked when sickness occurs. Since they themselves obtained a transient increase in chloride excretion, while our own results confirm those of Cori and Pucher, it seems desirable to give a brief preliminary account of our work, which is directed primarily to the problem indicated in the title to this note.

The only other paper that we have been able to find bearing directly on this problem is by Schlagintweit and Sielmann,[4] who state (we have only seen an abstract) that in severe disturbances following large doses of X rays there is a decrease in the chloride content of the blood, and that sodium chloride given in any form gives full relief. Dodds and Webster give no details as to the X ray dosage they employed, and we are unable to suggest an explanation for the disagreement between our results and theirs.

We have studied so far 12 cases. The first three, a case of sarcoma of the superior maxilla, a case of uterine fibroid, and one of carcinoma of the uterus involving the whole pelvis, were studied especially to see if there was any change of pH value of the urine which might indicate an acidosis. No such change was observed in these or the later cases; we have observed no production of ketonuria; and the second and third cases were examined specially for lactic acid excretion, and no increase was found. Our evidence tends to show no production of acidosis.

Conclusions as to Effects of Rontgen Ray Therapy.

At this time we saw Cori and Pucher's paper, and the remaining nine cases have been examined especially with a view to testing the accuracy of their results with chloride excretion. Our data will be published in full shortly. We do not yet regard them as sufficient to permit definite statements, but we have drawn certain tentative conclusions, and we quote below several abbreviated case reports supporting these conclusions, which are:—

1. Rontgen ray therapy in massive doses produces a definite lowering of urine excretion (confirmation of Dodds and Webster) and a definite chloride retention (confirmation of Cori and Pucher) when the upper abdomen is rayed. Radiation of other parts of the body produces less effect.
2. With radiation of the upper abdomen, where the previous chloride excretion is low, the tendency to sickness, other things being equal, is greater.
3. Preliminary feeding of sodium chloride daily, so that the chloride excretion is raised to ten or more grammes per day before treatment is commenced, with continued administration during treatment, prevents or lessens the sickness.
4. The blood chloride is not invariably affected, though sometimes the percentage is lowered.

Total nitrogen and phosphate results were too inconstant to permit conclusions, but there was usually a slightly greater nitrogen excretion during the radiation period.

Case Reports in Support of Conclusions.

CASE 1.—C. L., male, aged 58, with carcinoma of the first part of the transverse colon, the mass extending upwards in the region of the gall-bladder, with marked glandular involvement, was given X ray treatment confined to the right side of the abdomen. Two 13 cm. ports of entry were used, one anterior and one posterior. 150 k.v. with filters consisting of 0·75 mm. Cu and 1 mm. Al were used on the anterior port, and 200 k.v. with 1 mm. each Cu and Al on the posterior port. In all 16 m.a. hours were given by the fractional method, in six treatments spread over eight days. The chemical findings are shown in Table I.

TABLE I.

—	Urine volume.	Total N.	P_2O_5.	NaCl.
	c.cm.	g.	g.	g.
Feb. 27th (day preceding treatment)	1190	6·78	1·09	8·90
First day of treatment	1090	7·73	1·13	9·31
Average, next seven days ..	750	7·52	1·51	5·24
Day following last treatment..	1120	11·27	2·25	7·90

The patient was not sick and ate well throughout the treatment. The results show a definite chloride retention, but the lowest excretion figure (penultimate day of treatment) was still 3·82 g.

CASE 2.—Mrs. A. M., aged 40, with carcinoma of cervix, had had treatment six months previously with radium. Deep X ray therapy was advised to the whole pelvis. Her general condition was good. The "cross-fire" method of fractional dosage was employed, using two 10 cm. ports anteriorly and one 13 cm. port posteriorly. The factors used were 200 k.v., and a filter of 1 mm. each Cu and Al, with target skin distance 50 cm. In all 18 m.a. hours were given, divided into six treatments spread over eight days. The chemical findings are shown in Table II.

TABLE II.

—	Urine volume.	Total N.	P_2O_5.	NaCl.
	c.cm.	g.	g.	g.
Average—				
2 days preceding treatment	936	5·04	1·48	4·11
First 4 days of treatment ..	792	6·06	1·71	3·69
Next 3 days of treatment ..	1053	5·08	1·22	5·66

The patient ate well throughout the treatment and was not sick. There was at most a slight transient lowering of urine volume and chloride excretion. The effect was much less than in Cases 1, 3, and 5; the upper abdomen was not rayed.

CASE 3.—H. P., aged 57, had a mass in the epigastrium, and X ray examination with a barium meal showed a large gastric filling defect, involving the lower two-thirds of the antrum of the stomach, and suggesting an extensive new growth, with possible involvement of the liver. He was given at first nine treatments spread over ten days, using nine 10 cm. anterior ports and four 10 cm. posterior ports, in all 32·5 m.a. hours, the factors being 100 k.v., 30 cm. focal distance, and 4 mm. Al filter. X ray treatment produced an immediate decrease in urine volume and chloride excretion. There was vomiting on the second day of treatment, and thereafter for eight days the patient was nauseated and ate little. During this period the urine volume slightly increased, but the chlorides remained low. By the end of the first period of X radiation food was better taken, but chloride excretion remained low. Five days later, on account of the destruction of the formed elements of the blood, quartz-lamp treatment was given (on alternate days, commencing three minutes back and front, and increasing by three minutes per treatment to 18 minutes). There was an immediate beneficial effect on the blood. The patient ate better. But the chloride excretion dropped to a still lower figure, and was not much increased by giving daily five and then six grammes of sodium chloride by mouth. (We cannot explain this effect. We have tested lamp treatment alone on two other patients and have found no effect on chloride metabolism.) A subsequent period of X ray treatment, similar in degree, was not marked by any degree of sickness, but was accompanied by a further diminution of chloride excretion. The chemical findings are summarised in Table III., and, accepting the figure 3·80 as a *minimum* for the chloride obtained from diet, there would appear to be a retention of not less than 100 g. of sodium chloride during the observation period.

* Urine specimens incomplete. † At least.

After the second period of X ray treatment the patient was discharged from hospital. He was readmitted a fortnight later, his general condition being much worse. Laparotomy showed that the growth involved the whole of the stomach, and that gastro-enterostomy was impossible. He died six days later. During this period one 24 hours' specimen of urine was obtained, very small in amount, and showing no detectable trace of chlorine. Autopsy confirmed the original diagnosis and laparotomy findings.

The marked features of this case are the lessened sickness during the second period of treatment when much more chloride was being ingested, and the great apparent retention of sodium chloride. We have endeavoured to trace this chloride. Chlorine might be excreted in the fæces in undue amount, in the urine in organic combination (Cameron and Hollenberg have shown that normal urine contains no organic chlorine[5]), or through the skin with excessive perspiration. No excessive perspiration occurred. A sample of fæces examined for total chlorine during the second period of radiation showed no more than the normal chlorine excretion by this channel. The urine examined at this time contained no organic chlorine.

Bearing in mind the dry chloride retention which occurs in glomerular nephritis, with the accompanying fibrosis, and the fact that normally such tissues as skin, hair, and nails contain the highest chlorine content of any in the body, it seemed possible, as Dr. C. R. Gilmour suggested to us, that the chlorine might be taken up in the fibrosing of the tissues resulting from the radiation. Some of the carcinomatous tissue and also some kidney and muscle tissue of this patient were examined for total chlorine. It was high in all; it was not so abnormally high in the carcinomatous tissue as to offer a definite explanation of the chlorine retention observed. Though this explanation appears to be the most probable, yet if the retained chlorine can be regarded as anchored in some insoluble substance remaining in the body, then this would appear to be widely diffused. The blood chloride of this patient showed no definite change during treatment.

CASE 4.—J. C. L., aged 59, with carcinoma of the stomach, was, at the commencement of observation, excreting about 3 g. of sodium chloride per day. 5 g. were given by mouth daily throughout the observation period. On the ninth day he excreted 9·5 g. Three X ray treatments were given on the succeeding three days; his chloride excretion averaged 7·61 g. and the urine volume was not much affected. The average for the succeeding four days (no treatment) was 7·75 g. Then two further X radiations were given; chloride excretion averaged 8·70. During the whole period he ate well. On the third day of treatment he was slightly nauseated at breakfast, but otherwise showed no trace of sickness. The X ray dosage was less than in the previous cases, in all only 10 m.a. hours, with 150 k.v. His blood chloride previous to treatment was 0·50 per cent. The day after cessation of treatment the figure was 0·39, and next day 0·45 per cent. The corresponding blood-urea nitrogen figures were 12·9, 17·1, and 14·3 mg. per 100 c.cm. The samples were all taken just after the midday meal.

CASE 5.—I. K., aged 52, with carcinoma of the stomach, probably of the pyloric end, had had a gastro-enterostomy performed some time previously. He was in poor condition, frequently vomiting after meals. At the commencement of our observations he was excreting on a light diet from one to three grammes of sodium chloride per day. On May 29th the epigastric region was radiated through three 10 cm. ports, with 100 k.v., 30 cm. focal distance, 4 mm. Al filter, and 3·75 m.a. hours. On June 2nd the treatment was repeated, with 5 m.a. hours, and the other factors unaltered. His condition got steadily worse, the vomiting continued, and he ate very little. On June 6th, after the blood analyses were completed, sodium chloride was given by mouth, and the dose was steadily increased. On June 9th the patient's appetite commenced to return, and increased to the 12th; then it gradually lessened.

The blood and urine results, as contrasted with the sodium chloride intake (other than the slighter amounts ingested with food) are shown in Table IV. The blood samples were all taken shortly after the midday meal.

TABLE IV.

Date.	NaCl per cent.	Blood (per 100 c.cm.). Non-protein N.	Urea-N.	Urine. Vol.	Total N.	NaCl.	NaCl ingested.
		mg.	mg.	c.cm.	g.	g.	g.

5	0·50	75	34	790	11·65	0·81	—
6	0·43	115	—	940	—	1·48	10
7	—	—	—	660	6·73	3·96	12
8	—	—	—	1000	10·83	6·94	12
9	0·53	33	14·1	810	7·63	5·86	18
10	—	—	—	660	4·84	6·61	26
11	—	—	—	1950	10·84	22·78	29
12	—	—	—	1770	8·92	16·67	12
13	0·51	—	14·3	1350	8·97	11·50	6
14	—	—	—	1080	9·68	6·72	6
15	—	—	—	1110	12·65	4·75	6

It would thus appear that, following the second X ray treatment, the blood non-protein and urea nitrogen steadily rose, and the blood chloride slowly decreased. After four days' heavy administration of sodium chloride the values for these blood constituents became normal, while there was a concurrent improvement in the patient's condition with cessation of vomiting and development of appetite. The patient's temperature, which had become subnormal (96°–97° F.) returned to normal, and the pulse improved.

During the period June 6th to 10th inclusive the patient received 78 g. of sodium chloride by mouth, in addition to that contained in his food, while he excreted 24·9 g. in the urine and lost none by vomiting. Soap-sud enemas were given on the 6th and 8th, with paraffin by mouth at intervening periods for constipation. The chloride loss by this channel can only have been slight, as the complete return from an enema on June 14th contained only 0·15 g. NaCl. The urines of June 7th, 8th, and 9th were analysed for total chlorine, and gave figures agreeing within the limit of error with the chloride determinations. The sudden return of the chloride excretion on the 11th to a figure of the same order as the intake is striking.

These results support the second of our conclusions, and indicate that the sickness due to X radiation can be cured rapidly by massive administration of sodium chloride, while they afford definite evidence of a chlorine retention during the recovery.

Discussion of Results.

Assuming that our conclusions are correct it may perhaps be permitted to speculate very briefly on the cause of the chlorine retention, and the apparently beneficial effect of sodium chloride therapy. The observations on Case 3 indicate that the chlorine is definitely retained in the body, and not excreted through some unusual channel. A chloride retention occurs in œdema, and Anderson[6] has noted œdema following intensive Rontgen radiation. No such œdema was observed in Case 3; the large retention would necessitate an excessive œdema.

Vomiting suggests itself as a means of chloride loss, but in Case 3 there was marked retention over long periods during which no vomiting occurred, in Case 5 there was similar retention, and in Cases 1 and 4 with slight retention there was no vomiting at any time. An obvious source of error is diet variation. The diets of these patients were controlled as far as possible, and no slight variations would account for our results, especially those with Cases 3 and 5.

Such results suggest immediately a comparison with the chlorine retention which occurs in acute pyloric and intestinal obstruction, as shown in a recent series of papers by Haden and Orr.[7] Here also, in addition to the retention, there is lowering of blood chloride, with an accompanying increase in the non-protein and urea nitrogen, and here also the accompanying intoxication is ameliorated, and in some cases cured, by administration of large amounts of sodium chloride, and of sodium chloride specifically. Dixon[8] has confirmed this beneficial effect (though Copher and Brooks[9] are not altogether in agreement).

According to Haden and Orr the detoxication change can be represented by an equation (which we have slightly modified)—

$$X + n(NaCl) + n(H_2CO_3) = H_n.X.Cl_n + n(NaHCO_3),$$

where X is the toxin, and $H_n.X.Cl_n$ is non-toxic. Their cases show an increase in carbon dioxide combining power of the blood after sodium chloride administration such as would be indicated by the above equation.

Obviously, if X radiation produces a toxin which also reacts with sodium chloride, then, if the reaction proceeds sufficiently, there should be *not only* a chlorine retention, but also a lowering of blood chlorides. Our results, added to those of Cori and Pucher, strongly suggest the occurrence of the former, and they imply that at any rate in some cases Schlagintweit and Sielmann's statement as to blood chloride is correct (cf. Cases 4 and 5).

It seems desirable to make a further accurate comparison of the chemical events in the two conditions, and to consider the possibility of a common underlying cause, at any rate where the upper abdomen is concerned, especially since Warren and Whipple[10] emphasise the sensitiveness of the intestinal epithelium to short-wave X rays. Such further work is in progress.

We wish to thank those doctors of the Winnipeg General Hospital who have allowed us to make these observations on their patients.

THE DIAGNOSIS OF ADDISON'S (PERNICIOUS) ANÆMIA

BY A NEW OPTICAL METHOD.*

BY ADRIANUS PIJPER, M.D.,
PATHOLOGIST TO THE PRETORIA HOSPITAL.

Addison's anæmia is diagnosed on a combination of clinical symptoms, which are not pathognomonic, and changes in the blood, which are. Hurst[1] says:—

> "The most characteristic features of the blood in Addison's anæmia are now recognised as being the great inequality in the size of the red corpuscles—the anisocytosis—due to the presence of microcytes and megalocytes, and the increase in their average size in spite of the presence of some cells far smaller than the smallest cells found in normal blood."

Price-Jones has studied the size of red blood-cells.[2 3 4 5] He draws the outline of 500 cells of a dried film, magnified a thousand times, and measures these with a millimetre scale, up to ½ mm. The mean diameter of these 500 cells is taken to represent the average diameter of the blood-cells of the person tested. He found the mean diameter in Addison's anæmia larger than in health.[5] This was confirmed in an indirect way by Campbell.[6] Price-Jones has also recorded his results by means of graphs indicating the number of cells of each size. Applied to cases of pernicious anæmia this method gives extremely valuable results, confirmed by Hurst.[1] The method, however, entails too much work for regular clinical use.

New Method of Determining Size of Red Blood-cells.

I venture to call attention to another, much simpler method of detecting the changes in the red cells which are typical of Addison's anæmia. It can be executed with the apparatus available in most laboratories, and, although not giving the precise details of Price-Jones's graphs, it would appear that with it the diagnosis of Addison's anæmia can be made from an unstained blood film in a few seconds.

Principle of Method.—An ordinary blood film can be used as a diffraction grating. When a beam of parallel rays of white light strikes a diffraction grating at right angles, and a positive lens is placed at the back of the grating, a series of spectrums will appear on a screen placed at the back of the lens at its focal distance. The size of the spectrums is a function of the size of the elements of the grating. A blood film used as a grating produces circular concentric spectrums, and their size is an expression of the average diameter of the red blood-cells constituting the grating. The formula, which on physical grounds applies in such cases, is:

$$d = \frac{l\sqrt{4f^2 + D^2}}{D}$$

in which (d) is the diameter of the blood-cells, (D) the diameter of the coloured circle in the spectrum of

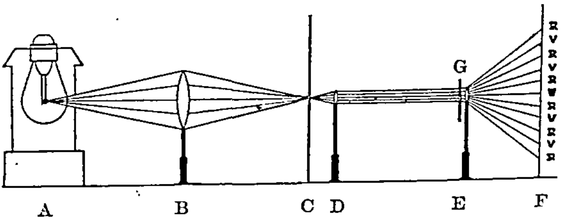
which (l) is the corresponding wave-length, and (f) the focal distance of the lens used. Twice the value of (l) must be substituted if the second spectrum is used for measuring purposes instead of the first. From the formula (d) can be calculated from (D). It is not claimed that a blood film forms a perfect diffraction grating, but for practical purposes it is surprisingly suitable.

Technique of Method.

In Fig. 1 the beam of parallel white rays is produced by focusing the source of light (A) (I use a Pointolite lamp of 100 c.p., but any other strong light or sunlight will do) by means of a condenser (B) on a narrow opening in the screen (C), and the emerging cone of light is rendered parallel by the small lens (D). A similar small lens (E) focuses the beam on the white screen (F). As it is necessary to exclude all other light from (F), it is convenient to work in a dark room, and (C) is suitably made the wall between the laboratory and the photographic dark room. The arrangement of the apparatus matters little, the only essential points are the parallel beam and a suitable focusing lens (E). Any lens with a focal distance of from 20 to 50 cm., and a diameter of from 1 to 2 cm. is suitable. The beam must be made to have a corresponding diameter of from 1 to 2 cm. A blood film placed at (G) will produce a series of three concentric circular spectrums round the bright white spot (W), the colours of which are indicated by the letters (R) and (V), meaning red and violet. Slight movements of the film will help to find the most suitable area to be exposed. The first spectrum loses its violet section in the central white spot (W), the second spectrum is complete and suitable for measuring, the third spectrum is rather pale. Permanent records can be obtained by means of Lumière's colour photographic plates. If a suitable area of 1 cm. diameter, where the cells are closely packed, is exposed, the number of cells enclosed is over a million. With a lens of about 30 cm. focal distance the second spectrum measures about 8 cm., and the diameter of its coloured circles can be estimated with an accuracy of about 1 mm. A red blood-cell measures about 8 microns. The diffraction method of measuring red blood-cells may therefore be said to permit the combination into one picture of the images of more than a million red blood-cells, all magnified 10,000 times. From the formula the mean diameter of over a million cells can be calculated with an accuracy of about one-tenth part of a micron.

FIG. 1.

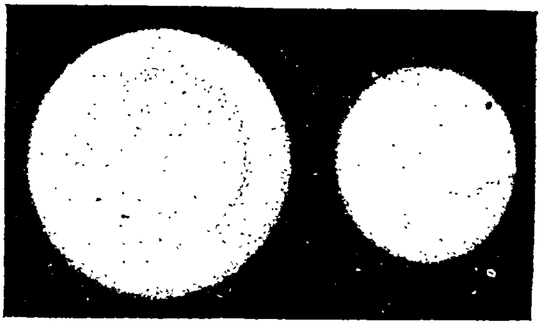


Practical Results of Method.

With a normal blood film and a focusing lens of 27 cm. focal distance the green circle of the second spectrum measured 74 mm. From the formula it followed that here the mean diameter of over a million normal red cells was 7·7 microns. Blood films from several normal persons showed only minor differences in this respect. These may be due to the diurnal variation in the size of the blood-cells described by Price-Jones.[3] Blood films made from one person in one sitting showed no such discrepancies. Fig. 2 (left) is a photograph of such a normal spectrum, taken with a lens of about 25 cm. focal distance. The dark ring is the blue and violet part of the second spectrum.

In Addison's anæmia the poikilocytosis will naturally prevent the formation of regular, bright spectrums, and the megalocytosis will tend to produce smaller spectrums than normal. The microcytes will again detract from the purity of the colours. Theoretically, therefore, blood films in Addison's anæmia should produce smaller and at the same time paler spectrums than normal blood. This is exactly what happened in the three cases of Addison's anæmia to which the method was applied.

FIG. 2.



Spectrums of normal blood (left) and of blood in Addison's anæmia (right).

These three cases presented the following features: Lemon colour of skin; general weakness; hæmoglobin 29, 32, and 40 per cent. respectively; red cells 2·5, 1·2, and 1·4 million respectively; poikilocytosis, anisocytosis, and polychromatophilia marked; microblasts and megaloblasts present but not always numerous; relative lymphocytosis; no free hydrochloric acid in stomach; large number of hæmolytic bacteria, mostly streptococci, obtained from duodenum; van den Bergh's indirect reaction positive. With blood films from these three cases and a focusing lens of 27 cm. focal distance the green circle of the second spectrum measured 52, 53, and 63 mm. respectively. According to the formula, therefore, the blood-cells measured 10·8, 10·6, and 9 microns respectively. In addition to this the spectrums were very pale, as can be judged from Fig. 2 (right), which is a photograph of one of them, taken under conditions identical to those of Fig. 2 (left). The dark ring is again the blue and violet part of the second spectrum. The thin blood of Addison's anæmia makes bad films. Normal blood diluted three times with serum made equally bad films, but the dilution had no appreciable effect on the size or brightness of the spectrums produced.

Neither fixing nor staining improves poor films. The spectrums may even become weaker thereby, and the second spectrum be too pale for measuring purposes, but in that case the red ring of the first spectrum can be employed instead. Blood films from 15 cases of anæmia, other than Addison's, were used as controls. They included cases of malignant disease and malaria, with hæmoglobin contents as low as 30 per cent. In not one of these cases were the size or nature of the spectrums in the least similar to those observed in the three cases of *Addison's* anæmia.

These results certainly seem to make the method worthy of further trial. Old stained films can be used for this purpose, but it must be remembered that these must not be exposed to a strong light for a long time, as this seems to affect the shape and size of the cells in some cases.

iated as disgraceful, and not regarded as patho- gically excusable by the offender. However this ay be, the prison medical officer, who to some xtent rightly measures his vocational success by he ease with which he gets into sympathetic touch ith his prisoner during the mental examination, nds some of his most disappointing cases in this spect among the perverts and inverts.

Realising this—realising, moreover, the difficulty dealing with the inherently disagreeable material an attractive form—I have nevertheless attempted this paper to make a few observations on exhi- itionism based on the clinical examination of a rge number of cases through many years, but rticularly on a recent series of 150 remand and ial cases.

I need offer no excuse for the importance of the ubject. Sexual offences generally are not only umerous, but may have far-reaching results. They equently involve as victims women, and children f both sexes, and are liable to fix vicious associa- ions in the minds of the suggestible, sometimes eaving a permanent impression thereon. And there s reason to believe that one has been able to trace a onnexion between such and a course of sex delin- uency lasting over some years.

Frequency of Sexual Offence.

During 12 months a record was kept by me of the umber of sexual offenders who were received for rial or on remand at Brixton Prison, in order to ave some guide as to the comparative frequency of his class of crime. The prisoners were all males; here were 291 cases, and the offences were as follows:

Indecent exposure	107
Indecent assault on females	69
Carnal knowledge and attempts	42
Indecent assault on males	37
Immoral soliciting	19
Unnatural offences	17

During the same period the total trial and remand prisoners received for other offences were 7401, and the sexual offences, therefore, were about 4 per cent. This number appears perhaps small, but it should be remembered they are all cases of some seriousness, whereas not a few of the others are comparatively trivial, such as those due to drink, vagrancy, and petty theft. An inquiry was made into the mental condition of the sexual offenders as a matter of routine, and in 101 of these cases the courts themselves had called for a report on their states of mind. In my experience the judicial authorities, and advocates practising in the criminal courts, are ever on the alert for evidence of mental disease or defect in these cases.

For the purposes of this paper the term exhibitionism is used as synonymous with indecent exposure of the genital organs. This does not appear to be always accepted. By some authors the term is only used in cases in which a psychopathic origin is diagnosed or assumed, but I would suggest that this is liable to lead the student to regard all exposure ases as pathological, which I shall endeavour to how is not the fact, and it also tends to bring about faulty perspective. It is somewhat remarkable at whereas in the criminal courts the adminis- tors of the law were so doubtful as to the mental lition of 60 of the 107 cases mentioned in the table as to call for a report thereon, yet text- on insanity usually either dismiss the subject lines or fail to mention it at all. In actual all such cases should, of course, be suspect eful examination into their mental condi- n conducted, for, as will be seen later, the r of those dealt with under the Lunacy Deficiency Acts is considerable, apart are merely subnormal or in need of ic treatment.

e Underlying Motive.

xual instincts, and morbid sexual bly more frequently met with in elsewhere. Putnam observes[1]:

"It is true, however, those who have not looked into the matter may think otherwise that, in the eye of science, perverted instincts such, for example, as an excessive passion for a person of the same sex, carried from the realm of thought into act, finds its analogue in many overdone or even quasi-normal relationships of daily life. It is a question of degree that is at stake, and although for purposes of punishment, prevention, public self-protection and social standards we must draw sharp lines, yet knowledge should make us prudent in passing scientific judgments."

To obtain a reasonably clear conception of many sexual crimes it seems to me important to bear in mind the composite character of the sexual instinct, and to regard many sexual offences as being related to the imperfect and irregular development of the components, due to pathological heredity and accidental associations, forming new sexual aims. When also circumstances prevent the release of sex energy along the normal channels, a diversion resulting in a criminal offence seems to take place through an infantile outlet in certain individuals already predisposed.

It will be well before discussing the exhibitionist to briefly consider the manner of the act of exhibitionism itself. This act consists, as I have said, in the indecent exposure of the genital organs nearly always by males to women, girls, or young children of either sex, by appearing from behind some bush, or whilst sitting on some seat in the public parks and commons, or from the entrance to a urinal or other narrow entry, or in the public highway, frequently by throwing open the coat by the aid of the hands in the pockets revealing the genital organ erect, or otherwise, outside the trousers. The act is sometimes committed indoors, the exposure being from a window, the lower part of which is often opened for the purpose. Less commonly it occurs in a railway carriage, tram, or 'bus to other passengers, not infrequently from a railway carriage as it passes a particular locality. The act is frequently repeated in the same district, at the same time of day, to the same person, a fact which has enabled the police over and over again to wait in hiding for its repetition, and then arrest the offender. It is often accompanied by lewd gestures and even masturbation may be indulged in, and sometimes female spectators are considerably frightened by the occurrence, and are very disinclined to give evidence in court about the matter, or to make their preliminary complaint to the police. Words sometimes, but rather infrequently, accompany the act. If used they are often indecent. A movement towards the woman is sometimes made, and at times an indecent assault is attempted. In some cases the act is apparently impulsive and spontaneous, in others premeditation and preparation can be demonstrated.

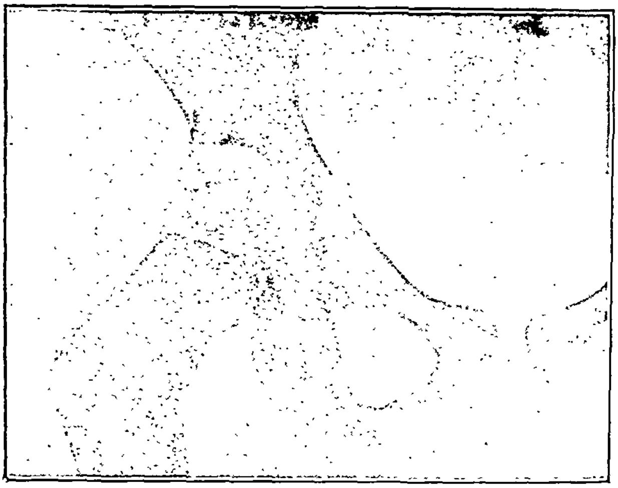
General Observations.

A few general observations on the 150 cases may be of interest before considering individual types. The offence is often so clearly abnormal that a high percentage of mental disease or defect might be expected in the family histories of the offenders. In only 19, however, was insanity or epilepsy or both, with or without intemperance, admitted. In five additional cases intemperance alone was recognised. These figures give the disappointing result so frequently found when making an inquiry into criminal cases, for not only are many unwilling to admit family defects, but several in the class from which most of the cases are drawn lose touch with their kinsmen early in life, and are unable to give any reliable information on the matter.

An analysis of the civil state of the offenders showed 90 were single, 57 married, and three widowers. Whilst the figures are too small to draw any conclusions therefrom, they do show a marked difference between those to whom regular sexual relations were available, and those whose comparative abstinence might be fairly assumed.

Points of special interest are: (1) Coincidence of pseudo-coxalgia and Köhler's disease. (2) Here the patient complained only of his right foot. His hips functioned normally, but clinical examination showed marked wasting of the right buttock and thickening of the corresponding trochanter, and the X ray revealed the abnormal picture described above.

FIG. 4 (Case 2).



Conclusion.

1. The study of these two cases, which were the only cases of either Köhler's disease or pseudo-coxalgia seen in the Meath Hospital during the past year, lends weight to Sorrel's advice to examine radiographically both hips and feet in all cases of either condition. 2. These two cases tend to support (but, of course, do not prove) the theory that the radiographical and clinical resemblance of Köhler's disease to pseudo-coxalgia is explained by a common ætiology. 3. I have met very few cases of apophysitis of the tibial tubercle, and those which have come my way have given a definite history of trauma and seemed to me to differ in no way from partial epiphyseal separation in other situations. Scudder may be quoted as taking a similar view, and Osgood lays stress on injury. The two cases noted above, however, were young to suffer from Schlatter disease so-called, and further study of them and similar cases will be necessary to establish or disprove a connexion between this condition on the one hand, and Köhler's disease and pseudo-coxalgia on the other.

GLYCOSURIA IN SUBACUTE NEPHRITIS.

BY H. A. COOKSON, M.B., F.R.C.S. EDIN.,
D.P.H. CAMB.,
PATHOLOGIST TO THE ROYAL INFIRMARY, SUNDERLAND;
AND
K. S. BROWN, M.B., CH.B. EDIN.,
ASSISTANT PATHOLOGIST TO THE INFIRMARY.

THE occurrence of glycosuria in the following case of subacute nephritis was found to be due to punctate hæmorrhage in the floor of the fourth ventricle.

S. S., a girl aged 19, was admitted to the Royal Infirmary on Dec. 11th, 1923, in an unconscious condition. There was a history of fits just before admission.

Previous Illnesses.—As a child she had corneal ulcers of eyes after birth, but was healthy afterwards, though later on she had measles and influenza. Patient did not menstruate until 17 years of age, and periods were subsequently irregular. Fourteen days previous to admission patient felt out of sorts and suffered from headaches, and consulted her doctor. She improved at first, but two days before admission she became worse, and at 6 P.M. was convulsed and comatose, and never properly regained consciousness. There was no history of epilepsy, poisoning, &c. Two uncles died of meningitis and an aunt from kidney trouble.

Condition on Examination (Dec. 11th, 1923).—Fits came on in succession, two or three at a time, without conscious intervals between. Pupils equal, contracted, reactive to light. Eyes deviated to left in a fit, and patient threw right arm, leg, and head about. These convulsive movements commenced with right arm and fingers. Knee-jerks were not elicited. Plantar response: Extensor on left and flexor on right. Blood pressure, systolic, 180; diastolic, 140. Pulse was full and bounding. There was œdema all over, especially face. There was retention of urine. A catheter specimen showed abundant sugar and albumin. The lungs were dull, and showed crepitations all over. There was evidence of cardiac distress. Dec. 12th: Pupils dilated. Eyes rolling. Temperature rising. Pulse very fast and thready.

Post-mortem Notes.

Body well nourished and dropsical. In the brain the convolutions are flattened and there is a subarachnoid hæmorrhage over the left motor area owing to a small vessel having given way. There is a small hæmorrhage in the fourth ventricle. The rest of the brain is normal except for minute hæmorrhages. Both lungs show œdematous changes and terminal bronchitis, &c. There are five or six ounces of fluid in each pleural cavity. The left side of the heart is hypertrophied. The valves are healthy, but there are signs of early vascular degeneration especially noted in the aorta. All the abdominal organs show evidence of dropsical changes, and there is free fluid present. The liver shows fatty changes and some venous congestion (chronic). Kidneys are diseased, and show acute and subacute changes. The pancreas showed no naked-eye changes, and histological examination did not disclose any degenerative or atrophic changes in the parenchyma, and the islets of Langerhans appeared normal. The urine showed evidence of nephritis, a very considerable amount of albumin being present; also sugar and acetone.

Summary.

The patient died of subacute nephritis, and that this had existed for some time there is distinct evidence. The sugar and acetone found in the urine are of scientific interest only; damage to the fourth ventricle being known to cause this condition.

We are indebted to Dr. J. B. Waters, honorary physician, Royal Infirmary, Sunderland, for the clinical notes of this case.

OBSERVATIONS ON EXHIBITIONISM.

BY W. NORWOOD EAST, M.D. LOND.,
MEDICAL INSPECTOR, H.M. PRISONS, ENGLAND AND WALES;
LATE SENIOR MEDICAL OFFICER, H.M. PRISON, BRIXTON.

(*With the permission of the Prison Commissioners.*)

SEXUAL offences, sometimes called, perhaps less happily, moral offences, seldom form the subject of an article in this country, and this is probably mainly on account of its distastefulness. But any investigation into the mental condition of any group of criminals is beset with difficulty also, for no sooner is a criminal action committed than the offender excuses his conduct, and subsequent arrest frequently causes denial of the action quite apart from any lack of confidence in the medical investigator. The offender, as a defence reaction, not infrequently endeavours to shut out from consciousness actual facts relating to the crime, and denies incontrovertible evidence as part of the repressing mechanism. Sexual offenders are particularly liable to react in this manner, and deny their offence, although they may be assured that an incriminating statement to the medical investigator will not affect them adversely. This untruthful denial of the act, whilst adding to the difficulty of the examination, may be a matter of some diagnostic importance, for an obsessional case usually admits and deplores his weakness, whereas a denial suggests shame for an act appreciated as disgraceful, and not regarded as pathologically excusable by the offender. However this may be, the prison medical officer, who to some extent rightly measures his vocational success by the ease with which he gets into sympathetic touch with his prisoner during the mental examination, finds some of his most disappointing cases in this respect among the perverts and inverts.

Realising this—realising, moreover, the difficulty of dealing with the inherently disagreeable material in an attractive form—I have nevertheless attempted in this paper to make a few observations on exhibitionism based on the clinical examination of a large number of cases through many years, but particularly on a recent series of 150 remand and trial cases.

I need offer no excuse for the importance of the subject. Sexual offences generally are not only numerous, but may have far-reaching results. They frequently involve as victims women, and children of both sexes, and are liable to fix vicious associations in the minds of the suggestible, sometimes leaving a permanent impression thereon. And there is reason to believe that one has been able to trace a connexion between such and a course of sex delinquency lasting over some years.

Frequency of Sexual Offence.

During 12 months a record was kept by me of the number of sexual offenders who were received for trial or on remand at Brixton Prison, in order to have some guide as to the comparative frequency of this class of crime. The prisoners were all males; there were 291 cases, and the offences were as follows:

Indecent exposure	107
Indecent assault on females	69
Carnal knowledge and attempts	42
Indecent assault on males	37
Immoral soliciting	19
Unnatural offences	17

During the same period the total trial and remand prisoners received for other offences were 7401, and the sexual offences, therefore, were about 4 per cent. This number appears perhaps small, but it should be remembered they are all cases of some seriousness, whereas not a few of the others are comparatively trivial, such as those due to drink, vagrancy, and petty theft. An inquiry was made into the mental condition of the sexual offenders as a matter of routine, and in 101 of these cases the courts themselves had called for a report on their states of mind. In my experience the judicial authorities, and advocates practising in the criminal courts, are ever on the alert for evidence of mental disease or defect in these cases.

For the purposes of this paper the term exhibitionism is used as synonymous with indecent exposure of the genital organs. This does not appear to be always accepted. By some authors the term is only used in cases in which a psychopathic origin is diagnosed or assumed, but I would suggest that this is liable to lead the student to regard all exposure cases as pathological, which I shall endeavour to show is not the fact, and it also tends to bring about a faulty perspective. It is somewhat remarkable that whereas in the criminal courts the administrators of the law were so doubtful as to the mental condition of 60 of the 107 cases mentioned in the above table as to call for a report thereon, yet textbooks on insanity usually either dismiss the subject in a few lines or fail to mention it at all. In actual practice all such cases should, of course, be suspect until a careful examination into their mental condition has been conducted, for, as will be seen later, the actual number of those dealt with under the Lunacy and Mental Deficiency Acts is considerable, apart from those who are merely subnormal or in need of psychotherapeutic treatment.

The Underlying Motive.

Everyone has sexual instincts, and morbid sexual instincts are probably more frequently met with in prison practice than elsewhere. Putnam observes[1]: "It is true, however, those who have not looked into the matter may think otherwise that, in the eye of science, perverted instincts such, for example, as an excessive passion for a person of the same sex, carried from the realm of thought into act, finds its analogue in many overdone or even quasi-normal relationships of daily life. It is a question of degree that is at stake, and although for purposes of punishment, prevention, public self-protection and social standards we must draw sharp lines, yet knowledge should make us prudent in passing scientific judgments."

To obtain a reasonably clear conception of many sexual crimes it seems to me important to bear in mind the composite character of the sexual instinct, and to regard many sexual offences as being related to the imperfect and irregular development of the components, due to pathological heredity and accidental associations, forming new sexual aims. When also circumstances prevent the release of sex energy along the normal channels, a diversion resulting in a criminal offence seems to take place through an infantile outlet in certain individuals already predisposed.

It will be well before discussing the exhibitionist to briefly consider the manner of the act of exhibitionism itself. This act consists, as I have said, in the indecent exposure of the genital organs nearly always by males to women, girls, or young children of either sex, by appearing from behind some bush, or whilst sitting on some seat in the public parks and commons, or from the entrance to a urinal or other narrow entry, or in the public highway, frequently by throwing open the coat by the aid of the hands in the pockets revealing the genital organ erect, or otherwise, outside the trousers. The act is sometimes committed indoors, the exposure being from a window, the lower part of which is often opened for the purpose. Less commonly it occurs in a railway carriage, tram, or 'bus to other passengers, not infrequently from a railway carriage as it passes a particular locality. The act is frequently repeated in the same district, at the same time of day, to the same person, a fact which has enabled the police over and over again to wait in hiding for its repetition, and then arrest the offender. It is often accompanied by lewd gestures and even masturbation may be indulged in, and sometimes female spectators are considerably frightened by the occurrence, and are very disinclined to give evidence in court about the matter, or to make their preliminary complaint to the police. Words sometimes, but rather infrequently, accompany the act. If used they are often indecent. A movement towards the woman is sometimes made, and at times an indecent assault is attempted. In some cases the act is apparently impulsive and spontaneous, in others premeditation and preparation can be demonstrated.

General Observations.

A few general observations on the 150 cases may be of interest before considering individual types. The offence is often so clearly abnormal that a high percentage of mental disease or defect might be expected in the family histories of the offenders. In only 19, however, was insanity or epilepsy or both, with or without intemperance, admitted. In five additional cases intemperance alone was recognised. These figures give the disappointing result so frequently found when making an inquiry into criminal cases, for not only are many unwilling to admit family defects, but several in the class from which most of the cases are drawn lose touch with their kinsmen early in life, and are unable to give any reliable information on the matter.

An analysis of the civil state of the offenders showed 90 were single, 57 married, and three widowers. Whilst the figures are too small to draw any conclusions therefrom, they do show a marked difference between those to whom regular sexual relations were available, and those whose comparative abstinence might be fairly assumed.

The age incidence shows an interesting and constant diminution in the number of offences for each successive decade, viz.:—

From 16 to 25 years of age there were	57	cases.
,, 26 to 35 ,, ,, ,, ,, ,,	43	,,
,, 36 to 45 ,, ,, ,, ,, ,,	29	,,
,, 46 to 55 ,, ,, ,, ,, ,,	14	,,
,, 56 to 65 ,, ,, ,, ,, ,,	7	,,

These figures are, I think, such as would be expected, bearing in mind the gradual diminution in sexual activity as age advances.

In 26 cases the prisoner had been previously convicted of a similar offence, but in some of these the offence had been committed many years before, an interval of 20 years being noted in one case. The great majority in fact had not offended in a similar manner before, or at any rate, had not been previously arrested on this charge. May we not fairly conclude that possibly imprisonment has acted as a deterrent upon many exhibitionists? I feel it frequently has been curative. In 21 cases one or more convictions for other offences were admitted, and of these five were for sexual offences.

Sixty-eight prisoners admitted the offence, less than half. In 44 cases the act had been repeatedly committed at or near the time of arrest according to the prisoner's own admission, or from the evidence. This is probably an under-estimate. The reasons given for the offence by the prisoner are various, an accidental omission to re-button the trousers after micturition being a favourite excuse, as is also drink. The more candid admit masturbation, or an effort by the exposure to debauch others to commit a masturbatory act upon them. Sex gratification, sexual invitation to, and a desire to cause sexual excitement in, some woman or girl, and phantasy indulgence are also not uncommon admissions.

Classification.

For practical purposes cases of exhibitionism can be divided into two main groups:—

I. The psychopathic including—		
1. Psychoses	7	cases.
2. Undeveloped psychoses	7	,,
3. Psychoneuroses	5	,,
4. Mental defectives	24	,,
5. Subnormals—i.e., high-grade uncertifiable defectives	9	,,
6. Visionaries	40	,,
7. Alcoholics	9	,,
	101	

II. The depraved including—		
1. The exposure as a preliminary to an attempt at carnal knowledge	2	cases.
2. The exposure as an attempt to debauch children to commit a masturbatory act upon the exhibitionist	12	,,
3. The exposure as an attempt to attract, excite, or invite a female	35	,,
	49	

It is well to remember that within the psychopathic group itself many cases might be placed under more than one heading, and that not uncommonly a psychopathic as well as a depraved condition may be traced in the same individual. In the classification given I have put each case under the heading to which it seemed fundamentally to belong. I have no doubt that a large number were over-sexed, but this I look upon as a contributory state.

It is clear, I think, from the figures that the majority of exhibitionists are psychopathic, but the question of legal responsibility is not so clearly cut. The largest group, the visionaries, are, I believe, most easily cured by a term of imprisonment, and sometimes by a fine; by this means they are frequently made to appreciate the value of reality, and the vanity of phantasy formation.

With the psychotic and defective, treatment to be in any degree beneficial must be carried out on other lines, and punitive detention be avoided as unsuitable.

The subnormal psychoneurotic alcoholic and unstable require individual consideration. It will be generally agreed, I think, that the depraved group well merit imprisonment, but in the mixed psychopathic and depraved the best course to recommend, if asked by the court, is often a matter of anxious consideration.

The classification I have come to adopt differs from those usually proposed, or used. Krafft-Ebing[2] in describing the mental state of the exhibitionist; mentions three groups: (1) Acquired states of mental weakness such as senile dementia, paretic dementia, and alcoholism; (2) epileptic, epileptiform, and neurasthenic states; (3) impulsive conditions connected with degeneracy. Thoinot and Weysee[3] speak of six groups: (1) Idiots and imbeciles; (2) general paralytics; (3) senile dements; (4) alcoholics; (5) deliria of various categories; (6) epileptics and degenerates.

I have purposely avoided the use of the term degenerate, although I am well aware authorities such as Magnan and others have used it in this connexion in the past, but as far as I am able to appreciate, the recorded cases do not connote any precise clinical entity. It is a common practice to refer to criminals vaguely as degenerates, a loose term, I submit, which tends to thwart clear thinking or psychological investigation.

The Psychotic Group.

Of the 150 cases which form the material for this paper 14 were psychotic, in half this number the psychosis was fully developed, two were general paralytics, two paranoiacs, two were cases of dementia præcox, and one of senile dementia. In one of the *paretics* the futility of an exposure which is so often marked when occurring in this disease was well shown. The patient was 48, a single man, and was charged with exposing himself in a tube station. Whilst awaiting outside the doctors' examination room on reception into prison the same evening, he again exposed himself to about 30 other prisoners, making at the same time a lewd suggestion. He had been spending money freely and foolishly for some months before arrest, was grandiose, and exhibited the usual physical signs and a positive Wassermann reaction and was sent to an asylum. In the other case of general paralysis the exposure was probably due to an inability to appreciate social convention.

One of the *delusional* cases said he exposed himself in response to an order to do so from the Almighty. He described a struggle he made not to submit to the command, but eventually did so and said that then he would have exposed himself to 50 people if necessary. He considered the act to be symbolic, but of what I could not ascertain. The other patient with systematised delusions of persecution exposed himself probably as a sex invitation to a passing woman on a country road.

Of the cases of *dementia præcox*, one exposed himself in a flagrant manner walking along one of the most important streets in the metropolis, and gave as his reason that seeing the women in the street excited him, and the exposure "eased his nature." The other case exposed himself on a road to the people journeying to the races, and the only exciting reason for the act appeared to be the sexual stimulus of seeing so many women driving past.

The case of *senile dementia* occurred in a professional man who had lived up to the time of the offence in an exemplary manner, but whose mental powers were recognised by his associates to have been failing for some months before the offence.

It is of some interest to note that none of the 150 cases were due to *epilepsy*. As a student one was taught the connexion between epileptic automatism and exhibitionism, and one does, of course, meet with it from time to time, as in the case of a professional man who when overworked was apt to become automatic and then exposed himself, but in my own experience these cases are not as frequent as they are dramatic.

Psychoneurotic Cases.

The five psychoneurotic cases form a much smaller group than the literature would lead one to expect. Many prisoners at first say they exposed themselves on the impulse of the moment, and could not help doing so. Mental analysis may support their account as regards the spontaneity of the act without confirming the irresistibility of the impulse. There is, of course, in this connexion a special difficulty in dealing with sexual offences, as both normal and abnormal sexual impulses are recurrent and in the over-sexed may be difficult to restrain; moreover, organic relief may result from whatever sexual act has been indulged in, but very many cases, which at first sight appear to be psychoneurotic, show on analysis no effort to control the impulse, no distress at giving way to the desire, and imprisonment cures them. Such cannot be regarded as psychasthenic. Actual cases are, however, met with from time to time, I believe, and as a probable example I would cite that of a man of middle age whose wife after several years of happily married life denied him any further sex relations, for reasons which I need not go into. Within 18 months he was thrice found guilty of exposing himself whilst sitting on an outdoor seat with his trousers undone, but an enormous pendulous abdomen must have partially, if not entirely, concealed his genitals. He admitted the offence, said he deplored it and struggled against its commission, that he realised he was ruining himself by it, but that it relieved him, and he alleged he could not control himself. His statements were supported by the honest manner in which he spoke of his offences, the fact that punishment had been ineffectual, and that his account volunteered the essentials of a psychasthenic act, which he would be unlikely to know of unless his statements were genuine.

I have already mentioned that the exposure frequently recurs at the same place and at the same time of day, and this is sometimes looked upon as some evidence of an obsessional impulse. In my experience I find it usually means the act is done to attract, excite, or invite some particular female who is known to be in the neighbourhood usually at that time, and is not the result of an impulse originating from within, but a reaction to a particular external stimulus which has been assiduously sought after.

Mental Defectives.

An important group of 33 cases is formed by the mental defectives with those subnormals whose defect was considered insufficient to permit of their certification under the Mental Deficiency Act. Their exposures may be due to a lack of appreciation of social convention, to be contributory to masturbation, to obtain sex gratification or stimulate phantasy, to attract, excite, or invite some female or child, and occasionally it appears to be due to an infantile pleasure in showing off, as in the case of a defective youth who stopped men and women in an important street in a provincial city calling their attention to his exposed penis. In another defective the act appeared to be a retaliatory insult to some girls who the defective said were accustomed to laugh at him in the street, probably on account of his foolish appearance. The exposure in this case seemed fairly comparable to the less offensive putting out of the tongue at times indulged in by children. Whatever the exciting cause, personal experience leads me to consider it almost certain that any sexual offence committed by a defective will be repeated unless institutional care is adopted.

The Visionary Group.

The visionaries form an important group of 40 cases. They are those who derive sex gratification from the exposure and accompanying phantasy which may be preceded by or result in erection, and is sometimes aided by masturbation. From statements of accused persons themselves, and from the evidence of police officers who have effected arrests during the act of exposure, there can be no doubt that exhibitionism may result in ejaculation. There can also be no doubt, I think, that in these cases sex gratification results largely from phantasy indulgence, which the exposure stimulates and reinforces, and to some extent seems to serve as a bridge connecting phantasy and reality.

The cases vary in their crudity: A man, aged 32, who had served some years in the army in India and had there indulged much in sexual relations with native women, on his return home married, but owing to the ill-health of his wife and on economic grounds practised coitus interruptus. Walking across a common he picked up a continental book the pictures of which excited him, he exposed himself to some children and eventually went on to masturbation. He admitted nocturnal emissions as the result of exhibitionist dreams. In another case a youth, aged 22, whose only sex experience appeared to be that he once saw a woman at the seaside undressing to bathe, exposed himself from a window in his home to a woman in her back garden. He took all his clothes off, he said, to make things seem more real and to assist his imagination as to what the woman would say and do if she was in the room with him. Full sex gratification resulted from the act and accompanying thoughts. A widower, aged 53, exposed himself to two women, and then went on to masturbation. He said the presence of a woman rendered the act more realistic, as one was present during coitus and her presence during exposure assisted his imagination. A lad of 17, addicted to masturbation, exposed himself and said he became very excited if he thought a woman was looking at him then. Another youth of 18 was charged with exposing himself on three occasions from a railway carriage passing a particular locality close to his own home. He said he thought a girl might be watching him, and that his act would make her blush, and if he saw her then looking at him exposed he would obtain full sex gratification. The case of a youth of 17 who exposed himself on a heath was of some speculative interest, for although the act was apparently assisting phantasy, it appeared from his statement possible also that it resulted from emotional depression consequent upon the knowledge that he was about to lose his employment. It was his only known or admitted delinquency, and it seemed that perhaps grief had acted as a sexual stimulant, as it is occasionally said to do, and of which Havelock Ellis[4] quotes examples. Whether, in fact, this was so or not I have little doubt that when an emotional outbreak occurs as a temporary relief from a harassing situation, various sex offences occur from time to time as a result.

The cases in the visionary group have this in common, that phantasy indulgence is prominent, and, as I have already said, is stimulated by the exposure, and although in two or three cases I am open to the criticism that I perhaps could not clearly show that the exposure was accompanied by phantasy, yet I am inclined to think that really in those cases it was but that the phantasy passed unrecognised.

Whether this be so or not, all are familiar with the enormous influence that imagination has on sexual acts. That it is able of itself to produce sex gratification seems undoubted. Havelock Ellis refers to such cases,[5] and Placzek[6] remarks: "Many men can have sexual intercourse with their eyes." Bearing in mind the phenomenon of ejaculatio præcox it can hardly be a matter for surprise that when exhibitionism is accompanied by vivid phantasy, relief from sexual tension may result in certain psychopathic individuals.

The Alcoholic Group.

The most important point of interest in this group would seem to be the small number of cases—viz., nine. In a few cases classified under other groups an alcoholic element seemed possible, but only in a few. In this group alcohol appeared in important relation to the exposure. It is a matter of common prison experience that sexual offences are very frequently attributed to drink by the offender, often as a face-saving excuse, but also often with some truth. My own impression is that sexual offences were much commoner when liquor was cheaper and restrictions absent, and the official figures show in support of this that in the year 1913 in England and Wales 866 men were convicted for indecent exposure, whereas in 12 months 1922–23 only 548 were so convicted. Some such figures were anticipated, and it seems only fair to attribute them as being due, at least to some extent, to the lessened consumption of liquor, bearing in mind the aphrodisiac action of alcohol, and its influence in causing loss of higher control. If liquor was as easily obtainable now as in pre-war times I believe we should find more cases of exhibitionism. When alcohol is associated with the exposure I believe a genuine confusion does in fact at times occur, but I do not think as frequently as is alleged. In some cases a latent tendency towards exhibitionism appears to become manifest under the action of alcohol.

The Depraved Group.

In considering this group, it is well to recollect Putnam's exhortation already quoted, which seems particularly applicable in this connexion. Before placing any case in this group of 49 cases I have taken the utmost care to arrive at the truth. I have already said that in two cases the exposure was apparently a preliminary to an attempt at carnal knowledge. In 12 I considered it due either to an attempt to debauch a child to perform masturbation upon the exhibitionist, or in a few cases it may have been preliminary to an indecent assault on the child happily prevented by an interrupter. There is no doubt a verbal invitation to masturbation is sometimes made, and pence for sweets also occasionally offered as a bribe. From such cases as these are drawn some of the park pests whose activities are indulged in chiefly in the summer months, when children unattended gather together to play in the public gardens and spaces.

The largest number of cases in the depraved group—35—consists of those whose exposure was made to attract, excite, or invite some woman or girl. Some distinction in the degree of turpitude can be made in different cases. Thus a married man, aged 36, engaged at work in a top room, saw in the corresponding room across the street two women dressing of a morning nude to the waist. He waved to them and they waved back. He then exposed himself to encourage them to further advances, to which, however, they did not respond. The room of a youth of 18 looked on to an orphan school, and the girls therein, aged about 14, were said to have waved and then lifted their clothes up to him, upon which he exposed himself and was seen by an onlooker. A youth, aged 16, exposed himself on three occasions to a girl passing his window, and said he did so as he had heard other lads discussing it as an efficient means of sexually exciting a girl. A man of 38, seeing two maids looking out of a window, exposed himself to them, and when they failed to notice him passed on. Somewhat different are those cases in which a man is attracted by a particular female, and eventually exposes himself to her. Thus a youth, aged 16, accustomed to frequent a certain coffee-shop, became attracted by the waitress; after several visits in which he had never spoken to the girl except to give his order, he one day found himself the only customer in the shop, and exposed himself to her, thinking, he said, that he might attract her. A married man of middle age and respectable position, wont to travel by 'bus to town of a morning with a particular girl, became attracted by her appearance, and eventually exposed himself to her on more than one occasion as he sat beside her in the 'bus hoping to excite her. A single man, aged 30, who was able to recall exhibitionist dreams, passed the same woman several mornings on his way to work. She took his fancy, and when she had passed him he looked back to find her doing the same. After this had recurred on several mornings he exposed himself to her when she looked back, hoping to further attract her. Neither had spoken to the other. Such, then, and of such is this group composed. More detailed accounts of individual cases will not be required: in many they are revolting, but in not a few one is reminded of the courtships of the farmyard, and the love antics and "showing off" indulged in by certain animals to arouse sexual desire in the females of their species.

Diagnosis in Mixed Cases.

In some mixed cases diagnosis is particularly difficult. A married man, aged 32, an Army reservist when war broke out, with a history of syphilis, was arrested for exposing himself to some children in the street. The police reported that when taken into custody he seemed dazed and unable to appreciate his position and was allowed bail the same evening and taken to hospital by his relatives. On reception into prison he produced an X ray photograph which showed a bullet in the occipital region, and inquiries showed that some seven years previously he had been wounded in the war and remained unconscious for some hours. Ultimately the bullet was removed, and later a cerebral abscess opened. His mental condition since recovering consciousness after the injury had never given rise to comment; there was no history of epilepsy or dream states. He alleged amnesia for the offence; this and the dazed condition noted by the police may have been genuine, but were not at all convincing, and it was not clear whether or no drink had any part in the case. I found, however, besides the evidence of an operation behind the ear that both optic discs were reddened and the edges blurred, particularly on the injured side, and the vessels were small. There was some lateral nystagmus of the eye on the wounded side, the other cranial nerves were unaffected. There were tremors of the hands, chiefly on the injured side, in which also dysdiadochokinesia was observed. The knee-jerks were normal and the Wassermann reaction negative. He had some years before been convicted of stealing and also for living on the earnings of prostitution. I sent a mental report to the court in the prisoner's favour and he was bound over. Several months later he was again arrested for exposing himself on three occasions from a window where he was employed to a girl in an office opposite. He again denied all recollection of the occurrences, but on this occasion it was quite clear from his admissions and the surrounding circumstances that he had full recollection of his actions: whilst asserting an amnesia he alleged at the same time an obsession for the exposures, and blamed a psycho-analyst for failing to cure him. He was obviously untruthful, and when examined in my room stared around him in an obtrusively vacant manner, which was absent when he thought he was unobserved in the ward; he assumed a stammer which he soon forgot to continue, coarse tremors of the hands became less marked when no notice was taken of them, a suggestion in his appearance that he had been drinking was stronger than on the first occasion, and his attitude and demeanour were generally unsatisfactory. After this further period of observation, and with the additional material to hand, I came to the conclusion that there was much depravity in his case. I found no support for the alleged amnesia or obsession, and was unable to report favourably. He was sentenced to a term of imprisonment, which so far appears to have been effectual, for he has not returned.

A Form of Regression.

There appears reason to consider that exhibitionism may be in certain cases a regression, and also that a large number of cases are related to a faulty development of the components of the sex instinct, in support of which I would note that in certain of the 150 cases there was an indication that some of the other components were also at fault. Thus a sadistic element appeared probable in a few, the exhibitionist following up his act by an indecent and violent assault on the woman; in one case a masochistic element seemed possible. Two other cases were frotteurs and the exposure was incidental thereto, and two were fetichists, one of whom on arrest was found to have a collection of female undergarments in his pockets.

In the following case exhibitionism, masochism, frottage, and self-flagellation were apparently combined. A business man in fair circumstances, a teetotaller, aged 61, with a grown-up family, lived happily with his wife. He had always been much over-sexed and commenced self-abuse when 11 years old, and continued it from time to time since. He stated that when aged 16 he had indulged in bestiality on three occasions, and in later years from time to time in frottage, purposely seeking crowds for that object. He denied any homosexual tendencies, but had always been much attracted to women. For years he had had the masochistic desire for his wife to hurt him during coitus, and also stated that during the last three or four years he had derived intense sexual excitement periodically by striking his genitals and lower abdomen against bushes which were capable of inflicting scratches upon him. He described in some detail his procedure in which he passed from bush to bush sometimes causing blood to flow. He had a double hernia, and might have excused his offence, as is common, by alleging he was attending to his truss or urinating. He, however, asserted with apparent truth that the exposure was the outcome of the bush flagellation, and this was not inconsistent with the police account of the occurrence; his account was not self-excusatory, he appeared earnest in his desire to become cured, and stated he struggled against his weakness but it overcame him. After its commission he was filled with repugnance and resolutions that it should never occur again. He said he had nearly been detected doing the same thing previously 12 months before. He was quite clear that during this curious performance he experienced no definite pain, and that the lower abdomen as well as the genitalia had to be struck.

Hirschfeld, quoted by Placzek,[5] who disagrees with him, thinks exhibitionism is always a pathological reaction to the fetichistic stimulation of stockings, legs, and other parts of the body. My own experience of these cases leads me to believe such stimulation is quite unnecessary.

Desire for Adventure.

I am myself satisfied that as certain men sally out for the set purpose of indulging in an alcoholic debauch, so others leave home to seek an exhibitionistic adventure. For instance, a recently married man left his office mid-day wearing a long mackintosh and gaiters. He went to a public lavatory and removed his trousers and carried them in an attaché case. He then travelled by conveyance into the next county, where his actions for some hours, although recollected, were undisclosed. On his return in the evening he exposed himself, still with his trousers off, by pulling open his mackintosh to two-attractive looking young women who were the last passengers except himself to get off the conveyance. When arrested, and asked why he had done it, he replied that "he felt like it."

Putnam,[7] in discussing the so-called "insufficiently dressed dreams," says: "Such dreams show what we ought in the interests of human sympathy to recognise, that between ourselves and those whom we stigmatise as exhibitionists, and therefore criminals, the difference, important as it is, is one of degree alone." And I would finally add this also. Medical men engaged in forensic psychiatry will find in these cases particularly the necessity to exercise their judgment as free from disgust as from compassion, lest the interests of the individual on the one hand, and the regard for public self-protection on the other be obscured.

Reviews and Notices of Books.

GYNÆCOLOGY WITH OBSTETRICS.

A Text-book for Students and Practitioners. By JOHN S. FAIRBAIRN, M.A., B.M., B.Ch. Oxon., F.R.C.P. Lond., F.R.C.S. Eng., Obstetric Physician to St. Thomas's Hospital. London: Humphrey Milford, Oxford University Press. 1924. Pp. 769. 25*s.*

IN this book Dr. Fairbairn has made an honest attempt to weld the twin sciences of obstetrics and gynæcology into one composite whole, and we may say at once that the attempt has succeeded well. The title is perhaps a little misleading in that obstetrics occupies considerably the greater part of the volume; this may be intentional on the part of the author, who desires to include under the term gynæcology everything pertaining to the health of womankind—even obstetrics.

The general arrangement of the book is admirable, and we note with pleasure certain chapter headings unknown to previous text-books; a prologue dealing with the history of obstetrics from the earliest times, the relation of the art to general medicine, and (especially) the new outlook to be acquired in its present-day study. Dr. Fairbairn never forgets the relation which the student of medicine must in due course bear to the State, and his endeavour has been to interest the student in the application of gynæcology to the public weal as well as to private practice. The author believes that the medico-legal and sociological subjects of medicine are more educative to the student if made part of his clinical training. All enlightened teachers will agree with this view. How many a newly-qualified practitioner discovers in the post-graduate school of experience that his portfolio of examination facts is but one asset in dealing with the realities of everyday life and practice.

In the matter of arrangment of contents the reader will receive one or two surprises. For example, puerperal sepsis is discussed under the heading of infections, and is placed between gonorrhœa and tuberculous lesions of the genital tract. Pelvic cellulitis and thrombo-phlebitis of obstetric origin are included in the same chapter. Probably this sequence is logically correct, but it will take time for the mind to divorce itself from its old associations. The same remark applies to such lesions as rupture of the uterus and perineal lacerations. Here true fusion of the twin subjects has occurred, for the reader will find their consideration deferred until the whole subject of genital trauma, including prolapse, is discussed under a chapter devoted to mechanical lesions. It is in matters such as this that the author has made a new departure; the only other combined text-book of obstetrics and gynæcology, that emanating from the Scottish schools of medicine, follows the more established lines of teaching. The reader will be well advised to make a careful study of the general arrangement of Dr. Fairbairn's book before attacking the subject-matter.

The volume is divided into eight parts. Part I. is devoted to normal anatomy and physiology, the chapter on physiology being particularly good. Part II. covers the whole of pregnancy, normal and abnormal. The excellent chapter on abortion includes a section dealing with medico-legal and ethical aspects. In connexion with the toxæmias of pregnancy and eclampsia biochemical problems are considered thoroughly. Perhaps in aiming at the ideal the author has introduced complexities which tend to render a difficult subject more difficult. Dr. Fairbairn is a strong advocate of psychotherapeutic methods in the treatment of hyperemesis gravidarum, and he states that for the last 15 or 20 years every case admitted to St. Thomas's Hospital for excessive vomiting of pregnancy has recovered on these lines without interference with the pregnancy. Part III. covers the well-worn ground of normal and year 1913 in England and Wales 866 men were convicted for indecent exposure, whereas in 12 months 1922–23 only 548 were so convicted. Some such figures were anticipated, and it seems only fair to attribute them as being due, at least to some extent, to the lessened consumption of liquor, bearing in mind the aphrodisiac action of alcohol, and its influence in causing loss of higher control. If liquor was as easily obtainable now as in pre-war times I believe we should find more cases of exhibitionism. When alcohol is associated with the exposure I believe a genuine confusion does in fact at times occur, but I do not think as frequently as is alleged. In some cases a latent tendency towards exhibitionism appears to become manifest under the action of alcohol.

The Depraved Group.

In considering this group, it is well to recollect Putnam's exhortation already quoted, which seems particularly applicable in this connexion. Before placing any case in this group of 49 cases I have taken the utmost care to arrive at the truth. I have already said that in two cases the exposure was apparently a preliminary to an attempt at carnal knowledge. In 12 I considered it due either to an attempt to debauch a child to perform masturbation upon the exhibitionist, or in a few cases it may have been preliminary to an indecent assault on the child happily prevented by an interrupter. There is no doubt a verbal invitation to masturbation is sometimes made, and pence for sweets also occasionally offered as a bribe. From such cases as these are drawn some of the park pests whose activities are indulged in chiefly in the summer months, when children unattended gather together to play in the public gardens and spaces.

The largest number of cases in the depraved group—35—consists of those whose exposure was made to attract, excite, or invite some woman or girl. Some distinction in the degree of turpitude can be made in different cases. Thus a married man, aged 36, engaged at work in a top room, saw in the corresponding room across the street two women dressing of a morning nude to the waist. He waved to them and they waved back. He then exposed himself to encourage them to further advances, to which, however, they did not respond. The room of a youth of 18 looked on to an orphan school, and the girls therein, aged about 14, were said to have waved and then lifted their clothes up to him, upon which he exposed himself and was seen by an onlooker. A youth, aged 16, exposed himself on three occasions to a girl passing his window, and said he did so as he had heard other lads discussing it as an efficient means of sexually exciting a girl. A man of 38, seeing two maids looking out of a window, exposed himself to them, and when they failed to notice him passed on. Somewhat different are those cases in which a man is attracted by a particular female, and eventually exposes himself to her. Thus a youth, aged 16, accustomed to frequent a certain coffee-shop, became attracted by the waitress; after several visits in which he had never spoken to the girl except to give his order, he one day found himself the only customer in the shop, and exposed himself to her, thinking, he said, that he might attract her. A married man of middle age and respectable position, wont to travel by 'bus to town of a morning with a particular girl, became attracted by her appearance, and eventually exposed himself to her on more than one occasion as he sat beside her in the 'bus hoping to excite her. A single man, aged 30, who was able to recall exhibitionist dreams, passed the same woman several mornings on his way to work. She took his fancy, and when she had passed him he looked back to find her doing the same. After this had recurred on several mornings he exposed himself to her when she looked back, hoping to further attract her. Neither had spoken to the other. Such, then, and of such is this group composed. More detailed accounts of individual cases will not be required: in many they are revolting, but in not a few one is reminded of the courtships of the farmyard, and the love antics and "showing off" indulged in by certain animals to arouse sexual desire in the females of their species.

Diagnosis in Mixed Cases.

In some mixed cases diagnosis is particularly difficult. A married man, aged 32, an Army reservist when war broke out, with a history of syphilis, was arrested for exposing himself to some children in the street. The police reported that when taken into custody he seemed dazed and unable to appreciate his position and was allowed bail the same evening and taken to hospital by his relatives. On reception into prison he produced an X ray photograph which showed a bullet in the occipital region, and inquiries showed that some seven years previously he had been wounded in the war and remained unconscious for some hours. Ultimately the bullet was removed, and later a cerebral abscess opened. His mental condition since recovering consciousness after the injury had never given rise to comment; there was no history of epilepsy or dream states. He alleged amnesia for the offence; this and the dazed condition noted by the police may have been genuine, but were not at all convincing, and it was not clear whether or no drink had any part in the case. I found, however, besides the evidence of an operation behind the ear that both optic discs were reddened and the edges blurred, particularly on the injured side, and the vessels were small. There was some lateral nystagmus of the eye on the wounded side, the other cranial nerves were unaffected. There were tremors of the hands, chiefly on the injured side, in which also dysdiadochokinesia was observed. The knee-jerks were normal and the Wassermann reaction negative. He had some years before been convicted of stealing and also for living on the earnings of prostitution. I sent a mental report to the court in the prisoner's favour and he was bound over. Several months later he was again arrested for exposing himself on three occasions from a window where he was employed to a girl in an office opposite. He again denied all recollection of the occurrences, but on this occasion it was quite clear from his admissions and the surrounding circumstances that he had full recollection of his actions: whilst asserting an amnesia he alleged at the same time an obsession for the exposures, and blamed a psycho-analyst for failing to cure him. He was obviously untruthful, and when examined in my room stared around him in an obtrusively vacant manner, which was absent when he thought he was unobserved in the ward; he assumed a stammer which he soon forgot to continue, coarse tremors of the hands became less marked when no notice was taken of them, a suggestion in his appearance that he had been drinking was stronger than on the first occasion, and his attitude and demeanour were generally unsatisfactory. After this further period of observation, and with the additional material to hand, I came to the conclusion that there was much depravity in his case. I found no support for the alleged amnesia or obsession, and was unable to report favourably. He was sentenced to a term of imprisonment, which so far appears to have been effectual, for he has not returned.

A Form of Regression.

There appears reason to consider that exhibitionism may be in certain cases a regression, and also that a large number of cases are related to a faulty development of the components of the sex instinct, in support of which I would note that in certain of the 150 cases there was an indication that some of the other components were also at fault. Thus a sadistic element appeared probable in a few, the exhibitionist following up his act by an indecent and violent assault on the woman; in one case a masochistic element seemed possible. Two other cases were frotteurs and the exposure was incidental thereto, and two were fetichists, one of whom on simple handicraft. As long as they are not troublesome they are simply left alone, whereas it is at least possible that the progress of the dementia might be delayed by painstaking occupation therapy.

Dr. Brill, who is responsible for this as for many similar translations, is, in spite of his long experience of the work, still an imperfect English scholar. He cannot shake off the German idiom, and quaint expressions combine with ambiguities to render the reader's task irritating. The following examples occur in the space of a few pages: "Careful oversight of the bladder [in general paralysis] is essential, as otherwise paradoxical incontinences remain concealed." Occasionally the text becomes utterly unintelligible. "In case of any kind of disturbances within the psyche the affects also must function differently than otherwise and may then generate morbid syndromes" (p. 493). "Mistaking an epileptic crepuscular attack of rage for the manic destructive impulse is avoided, among other things, by the absence of distractibility and flight of ideas (but one must not associate the circumstantiality in which the patient is not distractible and does not forget his goal as well as the liability to interruption, with the goal-shifting flight of ideas)" (p. 461). As this sentence stands it is sheer nonsense. There are few people outside a handful of advanced and earnest students of psychiatry to whom this book can be anything more than a work for occasional reference.

GROWTH.

By G. R. DE BEER, B.A., B.Sc., F.L.S., Demonstrator in Zoology and Comparative Anatomy in the University of Oxford. London: Edward Arnold and Co. 1924. Pp. 120. 7*s.* 6*d.*

THE phenomenon of growth is one of the most fascinating and inexplicable in the whole field of biology. The physical development of the individual has exercised the attention of the curious from time immemorial, but we are very little nearer understanding the essential problems concerned in the size of things than were our forbears. That this should be so is scarcely to be wondered at, for, as Mr. de Beer says, growth is a fundamental property of living matter; and life is the riddle of the world. The application of the experimental method has already done something to elucidate the problems, and much greater advances may reasonably be expected in the future. But it is essential that the general biological point of view should not be lost sight of in the specialisation which the subject tends to encourage. Mr. de Beer's book forms an admirable introduction to the study of growth. It is written clearly and simply, technical terms are avoided wherever possible, and the subject is presented from the broadest possible point of view. After a brief introductory chapter the author describes normal growth as exemplified in the frog and in other animals, and in plants. Reproduction, regeneration, and abnormal growths are next dealt with, and then such things as substances which speed up growth, the effect of external conditions on growth, size, rate of growth, differentiation, and age. The treatment of these various aspects of the question is necessarily elementary, but a useful bibliography is appended for the benefit of those who may wish to dig deeper in any particular field. There are several excellent illustrations.

INDUSTRIAL HEALTH.

Edited by G. M. KOBER and E. M. HAYHURST. Philadelphia: P. Blakiston's Son and Co. 1924. Pp. 1181.

THIS is a composite volume, the editors having called for assistance from many contributors, among whom are Italian, German, and English authorities, and, as is usual in composite books, the chapters are of uneven merit and a certain amount of overlapping occurs. The standard of the whole is good, one of the best parts being the prefatory sketch which contains historical retrospects of labour legislation in this country and in America. The sections dealing with carbon monoxide poisoning and caisson disease also deserve special mention for concise writing and up-to-date information; while the comparatively new study of occupational fatigue is clearly set forth by F. S. Lee. The book, however, leaves the impression that the authors are concerned more with the prevention of industrial risks than with the maintenance of health. The great architecture of health as a duty owed by industry to the community seems to be subordinated to consideration of patches and repairs needed to prevent leaks. Hence arises a tendency, manifested by many contributors, to present faulty and unconvincing statistics in proof of a connexion between the occurrence of this or that disease and some occupational influence; this is particularly in evidence on pp. 725–731, where tuberculosis mortality is displayed as a crude proportion of deaths from all causes without reference to age distribution. The short but excellent chapter by G. C. Whipple on statistical fallacies has evidently not been read by all his colleagues.

The arrangement of the subject-matter in the book calls for some remark. At one time particular industries are described—e.g., mining and stonecutting—with dysgenic influences and diseases referred to as incidental matters. This plan has the disadvantage, common to most medical works on occupation, that descriptions of processes appear which carry little meaning for the uninitiated and are unnecessary for the initiated. At another time occupational diseases—e.g., silicosis—are discussed with incidental reference to the several industries and processes in which they occur. This latter plan is more difficult to pursue since each writer needs to have a wide technical knowledge; nevertheless, it is far better calculated to disentangle the knot of cause and effect.

Taken as a whole, the volume merits praise. It is an effort in the direction which, in the editor's words, "results in the health and efficiency of employees being promoted, the profits of the manufacturer increased, and the quality of the products improved." It will remain for long as a work of reference.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXVII., No. 3. Pp. 217–348. July, 1924.—The Value of Naphthalene Emulsion in the Treatment of Experimental Intestinal Tuberculosis, by A. Stanley Griffith (Cambridge). The author has repeated Redman's experiments in a slightly modified form and has failed to obtain any evidence that naphthalene is of value.—In the next paper T. Redman (Liverpool) criticises Griffith's procedure and brings forward fresh experiments which, though not so striking as his original series, support his contention that naphthalene given by the mouth has a curative effect on infected guinea-pigs.—Blood Agglutination Tests on Fowls for Bacillary White Diarrhœa, by Edith Knight (London). Infected fowls can be identified by agglutination tests with *B. pullorum* and eliminated from the breeding stock with favourable effects on the occurrence of white diarrhœa in the young chickens.—The Formation of a Cancer-producing Substance from Isoprene, by E. L. Kennaway (London). Many attempts have failed to identify the substance or substances in tar which are active in producing epitheliomata in mice. The problem is simplified by using tar made by overheating isoprene, which excludes all bodies containing nitrogen; this tar is quite active.—Anæmia in Hens Associated with an Increase of Yellow Fat Pigment, by S. P. Bedson and Edith Knight (London). A description of a rare condition, possibly related to fowl leukæmia, which in a proportion of experiments is transmissible by inoculation.—The Nucleated Red Cells Found in the Blood in Pernicious Anæmia, by A. Piney (London). The real megaloblast has a characteristic structure and is found only in pernicious anæmia; it has been confused with the abnormal labour in a manner both interesting and convincing. Diagnosis and management are considered in the light of recent advances of knowledge, and the more purely academic problems of mechanism receive adequate but not undue emphasis. The rotations of the presenting part are well shown in a series of diagrams which would be useful for demonstration. Part IV., under the heading of "Lying-in Period," contains chapters upon the management of the new-born infant with a wealth of material and sound sense. Parts VI. and VII. are devoted to those subjects generally included under the term gynæcology, and the author has followed in general Prof. W. E. Fothergill's arrangement of diseases. It is in these sections of the volume that the reader will find the process we have called welding most developed. The inclusion of such subjects as puerperal sepsis and puerperal tears has already been noted. Similarly, Part VII. covers both obstetrical and gynæcological operations.

The author throughout has limited descriptions of instruments and operative procedures to such essential points as are necessary for an understanding of the methods of investigation and treatment, the details being left to be acquired in the only way possible—viz., by assisting in the operating theatre or labour ward, or by practising on the model. Much pathological detail usually introduced into text-books is omitted; the author defends his action on the ground that pathology has its own place in the curriculum, its own teachers, examiners, and examinations. Exception may be taken to this assertion in schools at which general pathology does not include the special pathology of the pelvic organs—e.g., endometritis, overgrowth of the endometrium in relation with the menstrual cycle, and such lesions as are included under the comprehensive term "chronic metritis." But the author's omission is logical. The concluding section of the volume is devoted to public health, social and ethical aspects.

Dr. Fairbairn has written a notable volume, valuable alike for its originality and breadth of outlook, a book which cannot fail to leave its impress upon current obstetric teaching, and which attains its object in presenting to student and practitioner modern views upon what the author would have us consider, not twin sciences, but one science.

A Memoir of William and John Hunter.

By George C. Peachey. Printed for the Author by William Brendon and Son, Ltd., Plymouth. 1924. Pp. 313.

The lives of the two Hunters will be ever of interest not only to members of the medical profession, but also to all those who enjoy a record of laborious search into the secrets of Nature, not for personal objectives, but with the desire to benefit humanity. Mr. Peachey prefaces his memoir of the brothers with an interesting account of the early teaching of anatomy in England down to the year 1746, in which year William Hunter began his first course of anatomical lectures, the advertisement of which (for there were no medico-ethical committees in those days) appeared in the London *Evening Post* of Sept. 16th, 1746. On this point Mr. Peachey has been able to correct a statement of former biographers that William Hunter's first essay at lecturing in London was made before the Society of Naval Surgeons, for that society was not founded until January, 1746–47, the first lecture being delivered on March 20th, 1746–47; as the year then began at Lady Day, William Hunter's lecture in September, 1746, was delivered some four months before the Society came into existence.

It may or may not be true to say "Great wits to madness sure are oft allied," but it is true that men of genius are often irritable, and the Hunter brothers were no exception, a fact which Mr. Peachey does not strive to conceal. They quarrelled with each other and both of them with their professional brethren, John being especially difficult. Early in his career we find him writing from Belle Isle, whither he had gone as surgeon to the expedition under Keppel in 1761, "My fellow creatures of the Hospital are a damned disagreeable set," and the whole unhappy contest with his colleagues at St. George's is set out in full in Appendix IV. of Mr. Peachey's book. No doubt Hunter was wrong in the manner in which he carried on the controversy, but the base motives imputed to him by his colleagues were certainly not in his mind.

There is one phrase in the book which needs explanation, at least for the general English reader. A note on p. 55, referring to William Hunter's career at Glasgow University, runs: "Mather adds that it was a bajan bursary of the value of £10 annually for four years." The word "bajan" is a variant of the French word *béjaune*—i.e., *bec jaune*—meaning a young bird, and was the title applied in a mediæval university to a freshman. The only blemish in the book is that there is hardly any account of the Hunters' parentage, but on the whole the memoir is well done and there is an excellent index.

Text-book of Psychiatry.

By Prof. Dr. Eugen Bleuler, Director of the Psychiatric Clinic, Zurich. Authorised translation by A. A. Brill, Ph.B., M.D. London: George Allen and Unwin, Ltd. 1924. Pp. 635. 25*s*.

This handsome volume is by no means a redundant addition to English psychiatric literature. In its arrangement and outlook it materially differs from works by English authors, and many new points of view, suggested or implied in its pages, may have a stimulating effect on minds accustomed to different teaching. The analytical point of view is constantly present throughout this book; but far from making extravagant claims for psycho-analysis as a method of treatment, he makes very little direct reference to it. This is an important omission; a modern text-book of such size and origin may rightly be expected to devote a chapter to this form of treatment, its indications, limitations, and dangers. Another unexpected feature is the inadequate treatment of toxæmia as a causal factor in insanity. No mention is made of focal infections, and puerperal psychoses are classed as schizophrenia. Evidence has fast been accumulating that infection plays an important part in certain forms of insanity, and even if Dr. Bleuler does not credit this evidence, in such a book as this he should at least state the case therefor. The physical accompaniments of mental disorder receive somewhat scant attention throughout the book, and the reader feels that its author is more a psychologist than a physician.

The greater part of the book naturally is devoted to the description of disordered mental states, and the immense volume of information comprised in these accounts constitutes its chief value. Numerous examples are quoted at length, and details are found here and there which must be new even to practising alienists. Perhaps the most notable of these accounts is that devoted to alcoholic psychoses, which extends over 50 large pages; the author, by the way, does not regard delirium tremens as a symptom of alcohol deprivation. A departure from the classification commonly accepted in this country lies in distinguishing ten varieties of insanity, including paranoia, folie à deux, and a number of others less familiar and not universally recognised as distinct types, under the heading of "Psychopathic Forms of Reaction (Situation Psychoses)." An important novelty on the practical side is the suggestion that cases of dementia præcox should only be given institutional treatment when there are special indications for it, such as violence or suicidal tendencies; the first essential is occupation, and this can better be provided at home. Such an arrangement might present great difficulties; on the other hand, attendants in institutions are often unable to devote the time required for teaching these patients some

THE LANCET.

LONDON: SATURDAY, AUGUST 23, 1924.

THE STATE OF PUBLIC HEALTH.

The Annual Report of the Chief Medical Officer to the Ministry of Health for the year 1923 is published this week, and contains the official records and statistics which are required from time to time in order to estimate the state of public health. It includes special references to particular diseases, and deals in general terms with the central actions which are being taken in regard to their prevention and the sanitary protection of the country. There is reference, often in considerable detail, to maternity and infant welfare services, insurance medical service, and the medical work undertaken in connexion with the Poor-law, while considerations of general sanitation include a special section on the relations of food to health and disease. The Minister of Health is charged with the task of supervising the administration by the sanitary authorities of the law dealing with food-supply, and the investigations in particular of the milk-supply of the country should have a valuable influence on public health and statistical records, and are accordingly given prominence in the Report.

The story which Sir George Newman has to tell is, on the whole, a cheerful one, and it need hardly be added that it is told effectively. The decline in the birth-rate is not so marked in 1923 as it was in 1922, but it is there to remind us that our total of population may be too much dependent upon reinforcement at the wrong end. The total death-rate is the lowest ever reported in the country, and there is a real triumph of preventive medicine behind an infant mortality-rate of 69. The number of cases of epidemic and infectious disease also compares favourably with the corresponding number in the report for 1922—namely, 344,183, against 422,949—but we are warned that, while facts and figures unite in giving us a promising record, unduly optimistic conclusions may easily be drawn. In any one year, for example, a particularly low mortality may depend on meteorological conditions or to a freedom from widespread epidemics whose absence from our shores cannot fairly be attributed in any large measure to national precautions. It is not a good thing to regard progress up to a certain point as an accomplished fact, for confidence in past performances may lead to a turning of the blind eye upon situations which, with due attention, could be further improved. The way to read the Report is as an interim document, which states what has occurred with reference to what should occur if the recorded efforts, successful up to certain levels, are persevered in and coördinated. If we consider the eighth section of the Report, for instance, which deals with the Poor-law Medical Service, we shall see at once how much work, both at the centre and periphery, remains to be done before a standard and pattern of administration and performance can be arrived at which will serve the general needs of the country. The section starts with the admission that year by year the problems of the Poor-law authorities have assumed greater importance, yet in regard both to domiciliary and institutional treatment the arrangements are sadly in need of overhauling, and the evidence of this need is very clearly exposed. For the provision of domiciliary treatment the guardians divide the areas for which they are responsible into a definite number of medical relief districts, and to each of these a district medical officer is appointed, being as a rule a part-time officer, though certain populous districts occupy the whole attention of a salaried officer. But the range of service expected from district medical officers has never been strictly defined, and the schemes made by Poor-law authorities for institutional treatment vary in different parts of the country in accordance with the size and needs of the areas, being influenced also by the extent to which in any given district the old intent to provide for all the needs of the destitute, non-medical and medical, has been replaced by organisation for the treatment of the sick. In all Poor-law areas institutional treatment is now provided either by the provision of separate infirmaries or by the allotment of definite wings of the workhouse to the treatment of the sick, and the accommodation which is thus forthcoming is capricious, being very much better in some places than in others. But undoubtedly the movement for conducting the Poor-law infirmary on lines comparable to those which mark the general hospital is growing in strength, and it is to be hoped that difficulties of organisation will not always prevent medical students from availing themselves of the facilities offered by the infirmaries for clinical instruction. But it will bring with it a further complication in respect of the position, voluntary or otherwise, of the medical staff of Poor-law institutions, and here we find every conceivable variety of arrangement. The smaller infirmaries are in the medical charge of practitioners engaged in general practice, save where the whole-time medical officer may combine the supervision of the institution with other public medical appointments. In institutions of medium size there may or may not be a resident medical superintendent, but in an increasing number of institutions the whole-time medical staff is supplemented by consultants employed under various conditions, and to differing extents, so that in large infirmaries the medical staff may include a medical superintendent, a group of assistant medical officers, and a full complement of consulting specialists. The number of professional and administrative problems suggested is, it will be seen, a large one, and only steady work in accordance with well-devised plans can deal with them effectively. Urgent as the position is, hasty action to meet a detail should not be asked for, unless it is clear that the course demanded would not embarrass a general policy.

To summarise what is itself a summary, and in places a summary of summaries, would result in nothing, and all medical men should read this Report, the general conclusions of which will be found on page 401. They will see that its essential message is the necessity (to use Sir George Newman's words) for concentration on the strongholds of disease, careful macronormoblast which occurs in other anæmic conditions.—The Control of the Virulence of the Pneumococcus, by J. F. Gaskell (Cambridge). The author recommends the use of solid egg media and broth made after the recipe of E. G. Murray, with occasional passages through mice.—The Modification of Diphtheria Toxin by Formaldehyde, by A. T. Glenny, Barbara E. Hopkins, and C. G. Pope. Toxin treated by formalin is relatively non-toxic, but retains high antigenic and immunising properties.—Changes in the Culture Medium During the Growth of *B. diphtheriæ*, by A. F. Watson and U. Wallace (London). The growth of both toxigenic and non-toxigenic strains in broth leads to an increase in the nitrogen precipitable by acetic acid and in the amino-nitrogen; the former fraction is closely associated with the toxin, if any.—The Concentration of Diphtheria Toxin, by A. F. Watson and U. Wallace. By precipitation by acetic acid toxin may be concentrated up to a hundred times or more and largely freed from extraneous matter.—The Pathology of Oxalate Nephritis, by J. S. Dunn, A. Haworth, and Nora A. Jones (Manchester). The intravenous administration of sodium oxalate to rabbits leads to a subacute catarrh of the first convoluted tubules with small doses; with larger doses to necrosis of the same cells with stasis and hæmorrhage in the glomeruli.—The Microcapillaries in the Liver and Bile-ducts, by G. S. Williamson and Innes H. Pearse (London). The epithelium of the gall-bladder and bile-ducts has an intracellular system of canaliculi similar to that described by the authors in the thyroid and continuous with the same arrangement in the liver parenchyma.—The Experimental Study of Gastrotoxic Serum, by J. Koopman (The Hague). The author could not obtain Miyagawa's results with auto- and iso-gastrolysins.—The Acid-fastness of the Tubercle Bacillus, by C. H. Browning and R. Gulbransen (Glasgow). The substance on which acid-fastness depends is very readily soluble in lipoid solvents which are acid.—The Parasites of Spontaneous Encephalitis in Rabbits, by G. C. Cameron and H. B. Maitland (Toronto) and C. Da Fano (London). In the experimental investigation of a case of encephalomyelitis by rabbit inoculation, the authors ran into a transmissible encephalitis of the rabbit with characteristic sporozoon-like parasites in the brain.—Agglutinins for Pfeiffer's Bacillus in Influenza and Other Diseases, by W. J. Wilson, J. H. Dunn, and E. M. McV. Blair (Belfast). Cases of influenza nearly always agglutinate Pfeiffer's bacillus; great care must be taken to use an agglutinable emulsion. Controls are negative except a few patients mostly with pulmonary affections.—The Dick Reaction in Scarlet Fever, by C. C. Okell and E. M. Baxter (London). Filtrates of hæmolytic streptococci from scarlet fever work like diphtheria toxin in the Schick reaction.—The Reaction of the Skin to Vaccinia Virus, by J. C. G. Ledingham (London). The response to vaccinia virus is primarily vascular, involving the endothelium of the vessels and their sheaths. The involvement of the epidermis is always secondary and there is no reason to include vaccinia in the epidermotropic infections.—Observations on the Effect of Diet on the Inflammatory Reaction, by J. A. Arkwright and S. S. Zilva (London). Guinea-pigs which are underfed, quantitatively or qualitatively, give much smaller inflammatory skin reactions to diphtheria toxin and other irritants than normal animals.—The Pentose Metabolism of Spontaneous Mouse Tumours, by B. R. G. Russell (London). Tumours seem to differ from normal tissues in their capacity to use xylose, and spontaneous do not differ from transplanted tumours in this respect.

QUARTERLY JOURNAL OF MEDICINE.—The July number contains the following articles: Achlorhydria and Hydrochloric Acid Therapy in Addison's (Pernicious) Anæmia, by Maurice E. Shaw. Investigations on the gastric secretion were carried out in seven cases of Addison's anæmia. It was found that achlorhydria was invariably present, and that its amount could be measured. About 2 drachms of acid. hydrochlor. dil. (B.P.) were required to supply the defect, and, if given by the "continuous" method, germicidal activity was restored to the gastric secretion.—Auricular Fibrillation in Thyro-toxic Conditions, by T. P. Dunhill, F. R. Fraser, and A. W. Stott. The authors record a series of 15 cases of thyro-toxic conditions associated with auricular fibrillation. Valvular disease was not present in any instance. They conclude that auricular fibrillation may at times have a thyro-toxic cause. In some of these cases a stable sinus rhythm followed partial thyroidectomy, and in others, in which fibrillation persisted after operation, normal rhythm was restored by the administration of quinidine. A series of electrocardiograms is included.—A Study of the Metabolism in the Under-nourished Infant, by G. B. Fleming and H. S. Hutchison. Metabolic observations were made upon infants admitted to hospital in various degrees of malnutrition. In the absence of gastro-intestinal disturbance no defect was found in the absorption of food, but it was not possible to estimate the absorption of carbohydrates. The utilisation of food also appeared normal in marasmus. Deficiency in quantity in diet is often the causative factor apart from gastro-intestinal disturbances, but in some cases marasmus occurs although neither of these factors is present.—Congenital Pancreatic Disease with Infantilism, by Cecil Clarke and Geoffrey Hadfield. The case recorded is that of a girl, aged just over 4 years, who died from broncho-pneumonia. She had suffered from fatty diarrhœa since she was 5 months old, and her appearance was that of a child 2 years of age. Post mortem, the pancreas consisted of a mass of fat containing a thin strand of gland tissue. Two plates are included illustrating the changes in the pancreas.—Tularæmia in Man from Laboratory Infections, by J. C. G. Ledingham and F. R. Fraser. Generalised infection with the *Bacterium tularense* causes a disease in rodents resembling plague, and man may be infected. It is confined to North America. Three laboratory workers of the Lister Institute, who were investigating the organism, became infected. The clinical condition of two of these cases is given in detail. An account is also included of serological tests for the recognition of the disease, and of the histological nature of the lesions in infected guinea-pigs and mice. These are well illustrated by two plates.—On Progressive Lenticular Degeneration (Hepato-lenticular Degeneration), by J. G. Greenfield, F. J. Poynton, and F. M. R. Walshe. The article opens with an historical and clinical account of the disease, which was first described by Wilson in 1912. A full record follows of the case of a girl of 15 who was under observation for some time until her death. Post mortem, the liver showed atrophic multilobular cirrhosis, and in the brain the corpus striatum was shrunken. Microscopically, the putamen and caudate nucleus were chiefly affected, and degeneration of nerve tracts in relationship to these bodies was seen. Corneal pigmentation due to granules in Descemet's membrane was also present. The article is illustrated by four plates, which show the clinical aspect of the patient and the morbid anatomy of the liver and brain.—Disturbance of the Acid-base Equilibrium of the Blood to the Alkaline Side: Alkalæmia, by Arthur W. M. Ellis. After an introductory account of the processes involved in neutrality regulation four cases of alkalæmia are described. In two of these large doses of sodium bicarbonate had been administered, and in the others there was intestinal obstruction high up. The urine in alkalæmia may be acid and contain ketone bodies. The most striking clinical manifestation is tetany, and it is probable that gastric tetany is of this nature and associated with a reduction of the plasma chlorides. The author suggests that the ketonuria of alkalæmia is due to anoxæmia, and that the latter is responsible for the symptoms which are characteristic of the condition. Clinically, the administration of 2 per cent. ammonium chloride solution per rectum has met with success.

EARLY MENTAL DISEASE: THE NEED FOR CLEAR THINKING.

IN making plans, however Utopian, for the better treatment of early insanity, it is well that we should understand for what precise forms of mental disorder the provisions are intended. It was observed by Dr. HENRY YELLOWLEES, in a discussion at Bradford which is reported elsewhere in this issue, that the "early" cases, for whose treatment there is at present so little satisfactory provision, are of several types entirely distinct both in aspect and prognosis. Of the adjectives distinguishing these types, by far the most inclusive is the term "incipient," which may indeed be applied to any form of insanity whatever, at the stage which the word denotes. Such a case, and those which may be described by the equally ambiguous epithet "mild," are not by any means necessarily curable, and Dr. YELLOWLEES evidently fears that the use of these terms may lead the public to expect recoveries which in many instances are exceedingly unlikely to follow, even from the provision of new institutions for early treatment. The true borderland case, on the other hand, does not become insane at all. This expression denotes a degree of mental disturbance insufficient to justify certification, non-progressive, and amenable, as a rule, to some form of treatment. Is there any criterion, such as the existence of delusions, which can be said to distinguish absolutely between mere depression and melancholia? Dr. G. W. B. JAMES, in the same discussion, raised a question of the greatest difficulty with which this is connected. He answered it by saying that he "believed it impossible, as a general rule, to certify a patient who intended to commit suicide unless there was other evidence of mental disorder." With this serious and unfortunate conclusion the majority of alienists will agree. Although deliberate suicidal intention is almost always associated with a grossly perverted outlook and sense of values; these cannot be said to constitute legal insanity, and the mere fact that suicide itself may in some circumstances be a sane act in the opinion of many people is, perhaps, a sufficient answer to this question.

Another point made by Dr. YELLOWLEES, which has an important bearing on the provision of early treatment, and on the attitude of the public towards it, is that acute, recent, recoverable cases are often much more abnormal in conduct than the chronic and hopeless insane. It is his experience that the public is being misled on certain of these points. It may safely be assumed that a proper comprehension of all the complex issues involved is a rarity even among the educated classes, and if by any avoidable means their conception of these issues is being perverted, it is certainly regrettable. There is no aspect of medical work in which public confidence and coöperation could be more useful, and none in which at present they are more difficult to obtain. Fully half the difficulties of lunacy administration depend in some way on public ignorance; many of the tragedies reported from the courts might have been averted if normal individuals had recognised in time that someone was of unsound mind, and had taken the necessary steps for his care. The daily press will have an opportunity, in reporting faithfully the proceedings of the Royal Commission on Lunacy Administration, of remedying to some extent the ignorance upon which so many of these difficulties depend.

ON SUTURES.

THE problem of suture materials is one which has taxed surgeons from very early times. Since AMBROISE PARÉ startled his scientific world by daring to ligate a blood-vessel, surgeons have continuously sought a material which would do what they require without introducing some element of secondary difficulty. In a septic wound to introduce a foreign body is to invite trouble, and even where the most scrupulous asepsis can be maintained it has always been evident that to leave unabsorbable material in a wound is a defect, however necessary, in surgical technique. With the introduction of catgut it was thought that the problem had at last been solved, but it was soon found that the difficulty of controlling the rate of absorption was considerable. However carefully catgut may be prepared, individual variations in absorptive power are enormous, and the "40 day" label in which the surgeon confides is a very rough index, considering the variation in rapidity of absorption in the muscles, the peritoneum, or the stomach, in the child and in the man, quite apart from anomalies in the catgut itself. Silk will certainly remain in the tissues, but surgeons have found to their cost that it may frequently gather to its folds seven other devils worse than itself in the shape of chance bacteria, and the end of that patient may be worse than the first. An ingenious compromise was suggested last week by Mr. D. MCINTYRE, whereby a fine filament of silk is embedded in a strand of catgut. The catgut is absorbed, and the fine silk appears to give rise to no trouble. The larger suture is easier to handle than fine silk, and has not the same tendency to cut through the tissues at operation. For, apart from the duration of suture materials, we have to consider the endurance of the material sutured, and it is to be feared that we often forget how slight this is. Generally speaking, there is no known means by which two portions of soft living tissue can be kept together artificially for more than 10 days. If union has not occurred within that time, the sutures cut through and the tissues fall apart. Indeed, in many cases five or six days is the longest period for which reliance can be placed upon sutures, not because they are absorbed, but because the material sutured disappears. It is said that certain materials such as kangaroo tendon and silk impregnated with mercury are not absorbed, but are invaded by living tissue cells and practically become embodied in the tissues. Were this the invariable result of their introduction the surgeon would have attained his ideal, but unfortunately it is not always the case. It is well, however, that we should recognise that the only permanent suture, if it is ever discovered, will be one that is gradually embodied in the living tissues, and that unless this condition is satisfied, no suture, whatever its durability, can hold soft tissues together for more than a few days.

THE Wellcome Historical Medical Museum at 54A, Wigmore-street, London, W., will be closed for cleaning and redecoration from Sept. 1st to 30th inclusive.

THE NIGHTINGALE TRAINING SCHOOL FOR NURSES, ST. THOMAS'S HOSPITAL.—In view of the ever-increasing scope of nursing work, the Nightingale Fund Committee has established a Traveller Fellowship, the holder of which is to visit Canada and the United States to examine and inquire into nursing, especially in relation to public health, and to report. It is felt by the committee that this experiment is quite in keeping with the pioneer spirit of the lady whose name the Fund bears. Miss Olive Baggallay has been appointed first Nightingale Travelling Fellow.

coördination and direction of means to ends, and systematic research. He prefaces this programme by laying stress on the need for the education of the people in hygiene. This education, we think, is now really progressing. In many directions where lay bodies are in charge of our local government there is an increased appreciation of the services of medicine, and a quicker perception both of what the prevention of disease means and of how the public can coöperate in it. The many publications dealing with questions of public health and medical service which have been issued at popular prices by the Ministry of Health for the last four years have played a great part in the instruction of all sanitary authorities, and the task of medical men has been lightened by finding that the community is not only willing to be guided but can be appealed to, when certain courses have to be taken, as reasonable participants in the work.

RHEUMATIC AFFECTIONS OF THE HEART IN CHILDREN.

The Ministry of Health stated recently that rheumatism costs approved societies each year something like £2,000,000 in sick benefit and is responsible for a loss to the nation of at least 3,000,000 weeks of individual work. Dr. Carey Coombs, who has done special research work on the subject, found that in Bristol 80 persons died every year of rheumatic heart disease, death occurring at an average age of about 35, preceded by five to ten years partial or complete incapacity for work, so that in any given year Bristol, with a population of 370,000, was maintaining about 500 persons incapacitated by this form of trouble. The average age of onset in two-thirds of a series of from 600 to 700 cases was between the tenth and fifteenth year. That these cases should be dealt with when the first manifestations show themselves is obvious, and it is encouraging to note the increased attention which is now being paid in many parts of the country to the treatment of this condition. In The Lancet of June 28th we drew attention to the excellent work which the Invalid Children's Aid Association is doing amongst children in the treatment of rheumatic affections of the heart. In 1918 the Association established the Edgar Lee Home at Stonebridge Park, and three months ago opened a similar home—Kurandai—at Hartfield, Sussex, for 50 children. The board of management at Great Ormond-street Hospital, London, have also taken a significant step in establishing a research department in which it is proposed among other things to investigate the phases of infantile rheumatism. At St. Thomas's Hospital also important clinical observations are being made on this condition, while in the provinces Birmingham and Bristol are tackling the question of heart disease in children in a practical manner. Dr. G. A. Auden, the school medical officer for Birmingham, reports that a society for the care of invalid children, especially those suffering from rheumatism, chorea, and heart disease, has been formed in that city. Ten beds are reserved in the cottage hospital of Much Wenlock for such cases, and over 40 other cases requiring prolonged treatment have been dealt with. An investigation into the after-history of 74 Birmingham children who had suffered from chorea showed that: (1) Out-patient treatment gave unsatisfactory results. (2) Home treatment was also unsatisfactory except in rare cases. (3) In-patient hospital treatment with prolonged stay gave good immediate results, but relapse was noticed in several cases shortly after the ordinary routine of life was resumed. (4) Short periods in the country, or one month in convalescent homes, gave ineffectual improvement with frequent subsequent relapse. (5) Where prolonged rest and open-air treatment were obtainable, the results had been very encouraging; a severe case resulted in a complete cure in four months, and so far there had been no relapse. The results altogether show that prolonged rest and open-air treatment give the best results, provided that the return to conditions of ordinary life is very gradual, with limited mental and physical strain.

In Bristol a number of typical cases of heart disease were investigated during the past year with a view to ascertaining to what extent proper provision is made for the treatment of the disease. These children were examined by one of the honorary staff attached to the city hospitals. It was found first that the child could not be kept in hospital nearly long enough for the heart to recover completely; secondly, that there were in the schools a number of cases which should be, but were not receiving any treatment whatsoever; with the result that in many cases lesions which might have been cured or greatly ameliorated were converted into serious and permanent disorders. The difficulty of providing hospital accommodation for such cases has been temporarily lightened by the offer of the Bristol Crippled Children's Society to provide the cost of dealing with a few cases for the next six months. There is no doubt that the question Birmingham and Bristol are now tackling is of primary importance in school hygiene. Treatment of defects follows so easily and readily these days upon their finding, thanks to the efficiency of the School Medical Service, that prevention of defect has become the centre round which all effort must circulate. The prevention of rheumatism and the treatment of its effect are in the forefront of points pressing for consideration in school hygiene. Special beds, with special medical supervision, are required for treatment, in addition to trained observations of a pathological condition about which in actual fact we know little enough. Much will result from attention focused on this subject provided adequate financial support is forthcoming. The problem is therefore clearly one for the education authorities to handle. As the school medical officer for Bristol, Dr. R. A. Askins points out, a disease which is more common than tuberculosis and is accountable for many more deaths and disabilities is one which ought to be tackled scientifically and thoroughly, and yet it is the one most commonly neglected, and it is to be hoped that other authorities will also take up this all important and pressing question of the treatment of heart disease among children of school age.

Dr. Carey Coombs suggests: (1) A clinic in which children with cardiac disorders may be inspected with a view to determining whether any special treatment is needed; (2) a school hospital where children with heart disease of moderate severity can be simultaneously educated and treated for periods of several months at a time; (3) it is desirable that long periods of rest in hospital should be available for children with severe cardiac rheumatism. We should like to add that any such institution should be under a constant medical supervision, for it is only by this means that the effects of regulated rest and exercise which are the essentials of such treatment can be scientifically noted and the treatment rendered effective.

signs on examination of the chest were those often observed in typhoid fever. There were sibilant râles distributed in a patchy manner over the lungs, without showing any special predilection for the bases or apices. The percussion note was not appreciably affected, the cough was moderate, and the expectoration slight. With tubercle bacilli found in the sputum and negative bacteriological and serological tests for typhoid fever, there could be no doubt as to the diagnosis which, in four cases, was confirmed by an X ray examination. Dr. Pellé notes that tuberculosis of the lymphatic glands and of the bones and joints may also make its debutant appearance under the guise of typhoid fever, and he records one case in which either typhoid or paratyphoid fever was diagnosed on three occasions within nine years, the disease not being recognised as tuberculosis of the hip till much valuable time had been lost. With regard to the coincidence of typhoid and tuberculosis, the author confirms the observation of Prof. Léon Bernard that the two diseases are seldom observed in the same patient. And when they are, the typhoid fever does not apparently stir the tuberculosis into renewed activity; in the only two cases in which Dr. Pellé has observed this combination there was no exacerbation of the tuberculosis, and as the Pirquet reaction to tuberculin remained positive after the onset of the typhoid fever, it may be assumed that typhoid fever differs in this respect from measles which often converts a positive into a negative Pirquet, at the same time as the tuberculosis shows clinical signs of rapid progress. The dietetic restrictions imposed on typhoid patients may not be fashionable a few years hence, but, as long as they are, mistaking tuberculosis for typhoid fever is calculated to inflict serious injury on a patient, one of whose first needs is plenty of nourishing food.

FACTORY HYGIENE IN 1923.

The Chief Inspector's report[1] gains additional interest this year owing to the existence of a Bill proposing to consolidate factory legislation passed since 1901, the date of the last consolidating Act. Developing industries create new hygienic problems. Dr. T. M. Legge contributes a chapter in which he records some rise in reported cases of plumbism, largely due to an increased call for electric accumulators set up by the advent of broadcasting, and to burning off paint in the developing industry of ship-breaking. Other unusual poisonings were due to arseniuretted hydrogen generated by the chance action of rain-water on refining dross, and to inhaling fumes of cadmium given off in carelessly melting ingots of this metal. Investigation by Dr. S. A. Henry of scrotal cancer among mule-spinners in Lancashire brought to light 145 cases ascribed to contact with shale oil and American oil. One of these was recently the occasion of a test case for compensation in a county court, and, as a correspondent points out on p. 408, the judge's ruling, if it stands, is likely to bring effective pressure on other employers to remove such risks for their workpeople. Dr. E. L. Middleton has continued his investigations on silica dust and reports danger from re-entry into workplaces of effluent currents discharged from exhaust draughts planned to remove dust as generated. Reference is also made to the first cases of poisoning from manganese dust recognised in this country; fortunately, the risk can be controlled, for seriously poisoned men are long-lived cripples. Perusal of the reports as a whole leaves the impression that the activities of the inspectorial staff are mainly devoted to preventing accidents by safeguarding machinery. Yet records are given to prove that "safety first" provides a far more effective method of prevention: thus, instances are quoted where safety first in one case progressively reduced a frequency rate from 32·3 in 1920, to 25·9 in 1922 and 23·6 in 1923, and in another a percentage of 9·4 in 1918 fell to 4·8 in 1922 and 4·0 in 1923. Meanwhile, the sum of reported accidents for 1923 has risen to a total of 125,551, being an increase of 27,565 over the total for 1922. This tendency to concentrate on the mechanical side of accident prevention no doubt results from employing engineers to administer the Acts, and from collecting statistics of accident occurrence to the exclusion of information as to the far greater amount of lost time resulting from sickness directly arising from occupational environment. Much more than half the report deals with accidents; less than four pages are devoted to overcrowding, temperature, lighting, and dust extraction, while welfare, statutory and voluntary, comes off little better with eight. The time of the existing medical staff is taken up with the occurrence of diseases peculiar to industry, such as anthrax, poisoning by lead, arsenic, mercury, benzol, aniline, and other chemicals, gassing and skin affections, which, when all are added together, cannot make up more than a fraction of the amount of sickness due to, say, rheumatism of occupational origin. Industrial diseases in their day have served a useful purpose, the purpose of paving the way for occupational hygiene. Dr. Legge's report contains an analysis of the 300,814 certificates of fitness issued during the year and the medical reasons for the 1·96 per cent. of complete and 4·37 per cent. of conditional rejections. Otherwise there is no mention in the report of occupational hygiene, although a number of progressive firms have already established highly successful medical services, and the Bill before the House provides means by which such service can supplement or replace that of the certifying surgeon. As small workshops decline in number (from 145,684 in 1922 to 140,850 in 1923) and larger factories increase (from 137,858 to 139,920) facilities for such service are rapidly growing. The Factory Acts are an essential part of our public health code, and the department which administers them is carrying on public health work, yet its staff of over 200 (trained as engineers, chemists, and the like) is only leavened by five with medical qualifications. Little wonder that the average employer who never sees a medical inspector fails to appreciate the value to his workers and, through them, to himself of occupational hygiene.

THE OUT-PATIENT OFFICER'S "AT HOME."

The first definition given to the word hospital in a well-known dictionary is "a place of shelter or entertainment," and in many respects that old meaning is much truer to-day of our modern hospitals than might be supposed, for the poor find there shelter, while the physician, particularly the out-patient physician, finds in the tragedy that is ever being unrolled before his eyes an element of comedy that is infinitely relieving in the sad environment. On this aspect of affairs at the Westminster Hospital Dr. Adolphe Abrahams contributes a graphic essay to a recent issue of the *English Review*. The hospital, he says, is an institution in every sense of the word. "The poor have not hospitals, they have 'their hospital,' their traditional family hospital. The medical officers change, but the institution and its tradition go on. Not only does the hospital minister to the sick, it does much more—it supplies some break in the monotony of narrow sordid lives, something to which to look forward. For one day in every fortnight at the out-patient physician's 'At Home' there is the opportunity afforded for a touch with sympathy, with refinement, with education, one might almost say, with decency." And the physician must possess all the qualities of the perfect host. "He must be all things to all men, and more particularly to all women. For they will come to him to discuss not merely their physical disabilities, but all the details of their lives and those of their relatives and acquaintances, to ventilate their grievances, to receive congratulations on their joys, to extract sympathy for their sorrows. He must express no surprise that Mrs. Riley's spectacles are optically unsatisfactory because she shares them with her

Annotations.

"Ne quid nimis."

COMPARATIVE ANÆSTHETICS.

There are one or two striking differences between the practice of anæsthetics in the United States and Canada and the arrangements with which we are familiar in this country. These differences are shown in the paper which we publish at page 411, and their effect on the administration of anæsthetics and on the progress of the art of anæsthesia is worthy of comment. It must be remembered first of all that just as conditions here vary, to a certain extent, in different parts of the country, and even in different hospitals in the same town, so in a vast country like America widely different customs prevail in the practice of localities which are thousands of miles apart. Consequently when, for purposes of argument or comparison, forms of practice are selected, it must be borne in mind that these particular forms of practice, although the routine in one city or one hospital, may be entirely absent from many other centres of medical education. In considering the practice of anæsthetics on the other side of the Atlantic the anomaly appears that conditions exist which invest anæsthesia with more importance than with us, while other conditions exist which suggest exactly the opposite. The latter are represented by the employment of nurses, and the former by a supply of whole-time paid anæsthetists, which is only faintly paralleled in Great Britain by our resident anæsthetists. For the employment of nurse-anæsthetists we can find no valid argument. However perfectly she may carry out the strictly limited task assigned to her, the nurse-anæsthetist cannot give to the surgeon the same security which he derives from a competent anæsthetist, who is also an experienced medical man. And as regards advancing the practice of anæsthetics, her opportunities or abilities are equally negligible. The paid whole-time anæsthetist presents a different problem. From the point of view of the institution which he serves, an adequate supply of whole-time anæsthetists presents the ideal condition. This is attained, we may assume, when every anæsthetic in the hospital, routine or emergency, is administered by an expert. This ideal of hospital practice, however, would entail serious educational drawbacks, and it may even be questioned whether from the broad outlook of the welfare of the public at large it is to be desired. The reason for this is that hospital education under the supposed ideal system would turn out a comparatively small number of experts instead of a large number of men fairly competent in anæsthetic work. The whole-timers would become, of course, experts, and presumably after a certain number of years in hospital would take up private anæsthetic practice. The average student and resident officer of the hospital, however, would have far fewer opportunities of rendering himself a capable anæsthetist than obtain under our present system. With things as they are he does not become an expert, but with average keenness and intelligence he can deal safely with ordinary methods of anæsthesia and discriminate between the cases which he can handle himself and those which he should delegate to an expert. At the same time it must be admitted that the American system is far more likely to lead, and does actually lead, to more experimental work and to more initiation of novel methods than we originate under our system. The most striking difference between the actual administration of anæsthetics in America and that usual in Great Britain is the complete elimination of chloroform from the former. This difference should render possible an illuminating comparison if reliable statistics of mortalities could be compiled. The American anæsthetists claim no exemption from occasional fatality. Yet they do not employ at all that drug to which the majority of anæsthetic fatalities in Great Britain are attributable. It would add greatly to our knowledge if we were provided from America with records showing in what way fatalities most commonly come about when chloroform is entirely ruled out of anæsthetic administration.

THE CASUAL CONTAMINATION OF FOOD.

We have received from a medical man a cutting from a Melbourne newspaper describing how a vendor of grapes was fined 20*s.* with 21*s.* costs for handling his grapes while he was smoking a cigarette and allowing the ash to drop on the grapes. Our correspondent suggests that Australia is probably ahead of us in this matter of the protection of food. That is so. Within a hundred yards of The Lancet offices we have seen trays of confectionery set down on the kerb overlooked by dust-carts in the act of being laden from the sanitary pails. There can be no doubt to the mind not drilled by daily custom that much carelessness is shown here in the handling of perishable food of all kinds. In the transport of meat, as the result of agitation, some improvement has recently taken place. A few firms now sell wrapped bread. Most people, however, are still content to take in their loaves of bread out of the basket slung on the back of the baker's boy and to eat crusts which have been rubbing against his dirty coat and shoulders. It is no uncommon thing to see the bread dropped on the road in transit from the cart to the basket. Even the dainty Parisian sets us no example in this respect. He buys his long loaves of bread by the foot and one sees him carry them home unwrapped in his hand or shoving a foot of bread into a not too cleanly pocket. Elsewhere in this issue (p. 405) our Paris correspondent has something to say on the subject of hygienic marketing in the French capital. It is perhaps more particularly perishable fruit which calls for better methods. Probably as the result of the substitution of motor for horse traffic the street dust, to which barrows of food are exposed, is less objectionable than formerly. Nevertheless, we imagine few people who are particular about having their food clean will care to purchase strawberries, raspberries, grapes, or plums from a street stall. It is difficult to see how adequate protection can be devised for the selling of fruits from street barrows. Careless and dirty methods are not peculiar to hawkers. Perishable articles of food are exposed in shop windows, and shop assistants in fruit and confectionery shops frequently handle their wares with the familiarity bred of contempt. Licking the fingers before handling the paper bag is not unknown. No doubt regulations could be devised to meet flagrant cases and the fear of penalty would serve to raise the general standard, but the greatest hope lies in the teaching of hygiene in the schools, and in the demonstration by the public that greater care in the handling of perishable food is always a paying proposition.

EARLY TUBERCULOSIS MASQUERADING AS TYPHOID FEVER.

Typhoid fever does much harm indirectly as well as directly, and its eradication will be indirectly beneficial in this—there will no longer be an excuse for mistaking early cases of tuberculosis for typhoid fever. The differential diagnosis is often discussed in the teaching hospitals, and most practitioners are alive to the risks of confusing one disease with the other, but so long as laboratory methods are not employed in every doubtful case, the clinician is apt to go astray, be his clinical acumen never so subtle. This is the lesson of a paper recently published in *Annales de Médecine* by Dr. A. Pellé, who during the past two years has observed as many as 14 cases of pulmonary and pleural tuberculosis begin with all the characteristic features of typhoid fever. Little wonder, therefore, that when he has found a history of typhoid fever in his cases of pulmonary tuberculosis (and in his experience such a history is common) he has come to doubt the accuracy of the diagnosis of typhoid fever. In all his 14 cases the physical reached as to how best to bring pressure to bear upon defaulters. Besides the information we have summarised, the statistical material gives food for thoughtful study.

THE DIAGNOSIS OF TYPHOID FEVER.

Dr. H. Löhr,[1] assistant at the Kiel Medical University Clinic, remarks that during the last two or three years it has been impossible to make the bacteriological and serological diagnosis of typhoid fever so early as before, although the patients come from the same district and the examination is carried out in the same place and under the same experienced supervision. In spite of repeated examinations of the blood, typhoid bacilli can often not be found until the fourth, fifth, or sixth week of disease, and agglutination is first obtained at the same time, while in other cases bacilli may be grown from the blood in the first week, but the agglutination titre does not rise to the level suitable for diagnosis until the fourth or fifth week. In some instances Widal's reaction does not become positive, even in the later weeks. The cause of this delay is not easy to determine. Perhaps the difficulty in growing the bacillus from the blood and the delay in agglutination are due to some hitherto unknown factors or to some change in the reaction in the diseased organism. The insufficient and vitamin-poor food of recent years may possibly have affected the antibody-forming function of the system. In very severe attacks, as in typhoid septicæmia, there is often a complete absence of antibody formation. On the other hand, the height of the agglutination titre does not bear any relation to the character of the attack. Löhr has found that by injection of non-specific protein substances such as milk or caseosan a low agglutination titre in a suspected typhoid case can be raised to a level available for diagnosis and even much higher. 5 c.cm. of milk or 2 c.cm. of caseosan are injected intramuscularly, and 12–24 hours later the blood is examined again by Widal's test. In most cases a rise of titre will be found. If, however, Widal's test is still negative after 24 hours, a larger dose of milk or caseosan should be injected, and the blood examined again in 12, 24, or 48 hours. According to the capacity of the individual to react it will be found that the agglutination titre rises from 1 : 30 to 1 : 200, 1 : 500, or 1 : 2000. In non-typhoid cases, on the other hand, the titre does not rise, unless they have been previously inoculated against typhoid. It is a well-known fact that the agglutination titre in the inoculated may rise after infections of other kinds, such as influenza, as has recently been shown by Curschmann, so that caution should be exercised in the diagnosis of typhoid fever in such cases.

THE CONQUEST OF YELLOW FEVER.

COMMENTING on the work done during the past year in fighting yellow fever in the Americas, the *Journal of the American Medical Association*, in a recent issue, states proudly that "if persons who are engaged in the promotion of preventive medicine ever waver in their faith that progress will attend the effort, their courage and persistence should be further sustained by the recent records of the continued campaigns against yellow fever." Yellow fever no longer exists in North America, Central America is almost free, and Brazil "has reached her final bout with the disease."[2] Previous to the latter half of the eighteenth century yellow fever was unknown in North America, but in 1793 the town of Philadelphia was ravaged by an epidemic which out of a population of 40,000 laid 4000 low. The disease apparently first occurred in the West Indies in 1647, and was then first described, but it received little mention in literature, medical or otherwise, until Charles Brockden Brown, of Philadelphia, published a vivid account of the scourge in his native town. His picture, like Defoe's story of the plague of London, is more illuminating from the historical point of view than helpful in the medical sense. In 1806, Thomas Paine, the great English-American Frenchman, writing on the subject, began to search strenuously for the cause of the disease, and it is interesting to note, as Dr. Arbour Stephens points out,[3] how far Paine's early theories foreshadowed the work that, almost a century later, was to result in the conquest of the disease, when Dr. Reid, of the American Army Medical Service, conducted his heroic investigations in Cuba in the summer of 1900. Paine was a philosopher rather than a scientist, but had his work been followed up by scientifically minded men, one feels certain that the truth would have been discovered much earlier than it was.

PRACTICE ABROAD.

ANYONE who has obtained a medical diploma entitling him to have his name printed in any section of the Medical Register becomes at once entitled to practise with little further formality over the greater part of the globe. The range includes, outside the United Kingdom, all the British Dominions and Crown Colonies, with the single exception of British Columbia. He will only require to present the prescribed evidence of the possession of degree or diploma of registration, and, if asked for, of good character, to the proper authorities in Australia, Canada, Ceylon, Hong-Kong, India, Malta, Newfoundland, New Zealand, the Union of South Africa, and the Straits Settlements, in order to enjoy the full privileges and responsibilities of medical practice. In British Columbia those registered prior to 1887 are so entitled; others must pass an examination before a local board, oral and written, in the final professional subjects. Two countries with which there is at present full medical reciprocity are, along with their colonies, also open to all who are on the British Register. These are Japan and Italy. Belgium was in the same category from 1915 to 1920, when a number of Brussels, Louvain, Ghent, and Liége graduates registered in this country, but in the latter year the Belgian authorities saw fit to discontinue the arrangement, and at the same time the Brussels practitioners' degree, an entirely different affair, was discontinued. There is no let or hindrance to record in the reciprocity with Japan; it has apparently worked harmoniously since it was instituted in 1905. But in Italy a temporary difficulty has arisen. Reciprocity was first established in 1901 when practitioners with Italian qualifications became entitled to all the privileges pertaining to British practitioners, but the latter were admitted only to practise amongst foreigners in Italy. In 1910, however, reciprocity became complete, and British practitioners began to enjoy unrestricted freedom of practice in Italy. Last November a registered British medical practitioner, desiring to practise at Ospedaletti, and with the knowledge of the Italian Consul-General in London, was refused permission to do so by the President of the Provincial Medical Board at San Remo, who informed him that he must first obtain an Italian medical diploma. It appears that the provincial authorities had not been apprised of the special agreement between the two countries, and that the matter is likely to be arranged, although those desirous of settling in Italy should bear these facts in mind.

In regard to practice in foreign countries where reciprocity is not in force, the circumstances vary in every possible degree. In China and Siam, for example, there are no regulations whatever restricting practice, whereas in pre-war Austria it was necessary to become naturalised before practice could be begun. In countries nearer home the regulations in France and Switzerland are of special interest; in both procedure has tended to stiffen of recent years. In France it is now necessary to obtain the baccalauréat and to go through the course of study culminating in a medical degree just as any husband, nor at Mr. Smith's explanation of his symptoms being occasioned by his occupation involving 'a lot of 'ead work' when Mr. Smith means that he carries a heavy basket of fish on his head." Above all, the physician must be possessed of patience, and the acid test of patience Dr. Abrahams describes as: a headache, a hot afternoon, a squalling child sent up with a very deaf old woman, who knows nothing about the patient. But it is just the idea of "hospes" that means so much in the voluntary hospital system, that preserves the intimate relationship between the hospital patient and the doctor, of which, as Dr. Abrahams says, this country is so deservedly proud.

AMMONIA AND CHLORINE IN THE DISINFECTION OF WATER.

SOME excessively polluted waters are not sterilised by chlorine supplied in the proportions usually found sufficient. This failure seems to depend on the presence of colloid or albuminoid matters, generally got rid of by sedimentation and clarification, which, according to Major C. H. H. Harold and Captain A. R. Ward,[1] protect the micro-organisms from the chlorine. This action they call "inhibition," and to get over it they propose to add to such water a quarter to a half part of ammonia per million prior to its exposure to chlorine gas, whereby the lethal action of the chlorine on the organisms is increased without any deterioration of taste. The authors observe that in civil life water can be stored to free it of colloids and organisms, but that there is no time for that on service in war, when it is hard enough to get water for daily use; and, besides, water must be sterilised at once. The usual measures proved efficacious almost everywhere, but anomalous results had occurred and lacked explanation at the time. Heavily polluted water being only used in dire necessity it was likely that just at the time there would be no laboratory available to make chemical and bacteriological observations. Therefore the authors set themselves to examine the question. They experimented at first with cholera, typhoid, dysentery, and other excremental organisms, exposing them to chlorine in various strengths for 45 minutes, and on finding *B. suipestifer* the most resistant of them all, they pursued their researches with this organism alone. Definite amounts of broth cultures and of chlorine were added to 200 c.cm. of autoclaved tap-water, the free chlorine remaining after 45 minutes was estimated, the difference, or "deviation," i.e., the amount gone into combination, being a guide to the killing power of the mixture. The deviation was uninfluenced by one kind of organism more than by another, but it was affected by the amount of broth present. Inhibition occurred in the presence of colloids, excess of organisms, fæcal or vegetable matter. When ammonia, about one-third part per million, was added 15 minutes before the chlorine, there was more deviation and the killing power was increased. Rideal showed that ammonia compounds are specially penetrative. Organisms or colloids take up first ammonia and then chlorine; chloramine or other chlorine-ammonia compounds of high coefficient are produced in situ where they exercise their maximum effect. The paper should be widely read by all interested, as it has important bearing on safe campaigning.

THE FIRST ORTHOPÆDIC CLINIC IN HOLLAND.

IT is remarkable that orthopædics have hitherto received so little attention from the medical profession in Holland, but this condition is likely now to be remedied by the opening, at Leiden, of a new orthopædic clinic—the first in the country. For more than ten years a number of infirmary buildings have been under construction in Leiden, supplied with laboratories, clinics, and dispensaries for every branch of medicine at a total cost of some £1,250,000. One of the buildings, which was originally designed for a fever hospital, has been allocated to the Society for the Welfare of the Crippled and Disabled. This hospital has accommodation for 40 beds, 20 of which will be paid for by the Government and will be used for teaching purposes. Dr. Murk Jansen, who is now lecturer in orthopædic surgery at the university, has been appointed director. Many difficulties had to be overcome before this project could be carried out. The strong opposition to the establishment of the clinic on the part of some surgeons is noteworthy, our Dutch correspondent writes, as giving an idea of the old-fashioned professional outlook in Holland in certain directions. The surgeons there have continually opposed the separation of any branch of medicine from surgery, and for this reason it took a long time before oto-rhino-laryngology, dermatology, and urology became separate specialties. For the same reason, too, there are in Holland no surgeons who specialise in surgery of the abdomen or brain. It must be remembered that for many years in all the British medical centres specialism was looked at with considerable suspicion, one fact being insisted upon and another fact suppressed. It was continually pointed out that there could be no sound specialism that was not founded on general medicine, but it was a long time before it was allowed that progress along special lines would be most surely arrived at by special work. The first is true, but the second is no less true. The establishment of the new clinic, under an orthopædic surgeon so well known as Dr. Jansen, should do a great deal to further in Holland the development of this branch of medical science.

COMPULSION IN THE TREATMENT OF VENEREAL DISEASE.

THE experiments on compulsory notification of venereal diseases abroad are being watched with keen interest at home. Some time ago the journal of the National Council for Combating Venereal Diseases published results achieved by the methods in force in Australia and Canada, and replies received to a questionnaire issued to State and public health departments in August last appear in its pages for July.[1] In *Queensland*, of the 568 cases notified for failure to continue treatment, 365 resumed after being warned, 4 were summoned (of whom 3 then resumed treatment), and 4 were brought before the court and fined. In Queensland it seems that in general the infected are only too willing to continue treatment, it is the nomad population which defaults. In *Tasmania* four defaulters resumed after being followed up by an official of the department and no cases were brought before the court. In Tasmania notification and compulsory treatment has, it is stated, not led to concealment, but yet has not achieved the good results expected. The tracing of contacts has proved quite unsuccessful. In *Victoria*, of the 6599 cases in six years who discontinued treatment, 3099 were traced and 3028 resumed, 71 were summoned (63 of them then resuming treatment), and 8 were brought before the court. The fear of publicity is felt in Victoria to have had some effect in causing concealment of disease, but the notification of a defaulter by name has not diminished attendance. In *West Australia*, of 320 defaulters 232 were traced, 24 were brought before the court, 16 cases being withdrawn, and 8 were fined. Here notification and compulsory treatment has not led to concealment or diminution of attendance, although wrong addresses are given which lead to difficulty in tracing defaulters. In *Ontario* 5 per cent. of cases discontinued treatment too soon; the scheme has not led to concealment or to diminution of attendance. In *Quebec* no legal measures are taken to induce patients to continue treatment, and it is felt that even confidential notification prevents the patient from coming to the clinic. It is evident that the effect of compulsion in the treatment of venereal disease is not proving easy to assess, and although the steps taken to deal with those who discontinue treatment have achieved a large measure of success, unanimity has not yet been reached as to how best to bring pressure to bear upon defaulters. Besides the information we have summarised, the statistical material gives food for thoughtful study.

THE DIAGNOSIS OF TYPHOID FEVER.

Dr. H. Löhr,[1] assistant at the Kiel Medical University Clinic, remarks that during the last two or three years it has been impossible to make the bacteriological and serological diagnosis of typhoid fever so early as before, although the patients come from the same district and the examination is carried out in the same place and under the same experienced supervision. In spite of repeated examinations of the blood, typhoid bacilli can often not be found until the fourth, fifth, or sixth week of disease, and agglutination is first obtained at the same time, while in other cases bacilli may be grown from the blood in the first week, but the agglutination titre does not rise to the level suitable for diagnosis until the fourth or fifth week. In some instances Widal's reaction does not become positive, even in the later weeks. The cause of this delay is not easy to determine. Perhaps the difficulty in growing the bacillus from the blood and the delay in agglutination are due to some hitherto unknown factors or to some change in the reaction in the diseased organism. The insufficient and vitamin-poor food of recent years may possibly have affected the antibody-forming function of the system. In very severe attacks, as in typhoid septicæmia, there is often a complete absence of antibody formation. On the other hand, the height of the agglutination titre does not bear any relation to the character of the attack. Löhr has found that by injection of non-specific protein substances such as milk or caseosan a low agglutination titre in a suspected typhoid case can be raised to a level available for diagnosis and even much higher. 5 c.cm. of milk or 2 c.cm. of caseosan are injected intramuscularly, and 12–24 hours later the blood is examined again by Widal's test. In most cases a rise of titre will be found. If, however, Widal's test is still negative after 24 hours, a larger dose of milk or caseosan should be injected, and the blood examined again in 12, 24, or 48 hours. According to the capacity of the individual to react it will be found that the agglutination titre rises from 1 : 30 to 1 : 200, 1 : 500, or 1 : 2000. In non-typhoid cases, on the other hand, the titre does not rise, unless they have been previously inoculated against typhoid. It is a well-known fact that the agglutination titre in the inoculated may rise after infections of other kinds, such as influenza, as has recently been shown by Curschmann, so that caution should be exercised in the diagnosis of typhoid fever in such cases.

THE CONQUEST OF YELLOW FEVER.

COMMENTING on the work done during the past year in fighting yellow fever in the Americas, the *Journal of the American Medical Association*, in a recent issue, states proudly that "if persons who are engaged in the promotion of preventive medicine ever waver in their faith that progress will attend the effort, their courage and persistence should be further sustained by the recent records of the continued campaigns against yellow fever." Yellow fever no longer exists in North America, Central America is almost free, and Brazil "has reached her final bout with the disease."[2] Previous to the latter half of the eighteenth century yellow fever was unknown in North America, but in 1793 the town of Philadelphia was ravaged by an epidemic which out of a population of 40,000 laid 4000 low. The disease apparently first occurred in the West Indies in 1647, and was then first described, but it received little mention in literature, medical or otherwise, until Charles Brockden Brown, of Philadelphia, published a vivid account of the scourge in his native town. His picture, like Defoe's story of the plague of London, is more illuminating from the historical point of view than helpful in the medical sense. In 1806, Thomas Paine, the great English-American Frenchman, writing on the subject, began to search strenuously for the cause of the disease, and it is interesting to note, as Dr. Arbour Stephens points out,[3] how far Paine's early theories foreshadowed the work that, almost a century later, was to result in the conquest of the disease, when Dr. Reid, of the American Army Medical Service, conducted his heroic investigations in Cuba in the summer of 1900. Paine was a philosopher rather than a scientist, but had his work been followed up by scientifically minded men, one feels certain that the truth would have been discovered much earlier than it was.

PRACTICE ABROAD.

ANYONE who has obtained a medical diploma entitling him to have his name printed in any section of the Medical Register becomes at once entitled to practise with little further formality over the greater part of the globe. The range includes, outside the United Kingdom, all the British Dominions and Crown Colonies, with the single exception of British Columbia. He will only require to present the prescribed evidence of the possession of degree or diploma of registration, and, if asked for, of good character, to the proper authorities in Australia, Canada, Ceylon, Hong-Kong, India, Malta, Newfoundland, New Zealand, the Union of South Africa, and the Straits Settlements, in order to enjoy the full privileges and responsibilities of medical practice. In British Columbia those registered prior to 1887 are so entitled; others must pass an examination before a local board, oral and written, in the final professional subjects. French student would have to do. There is no privilege accorded to medical diplomates as such. In Switzerland it is now obligatory to pass all three professional examinations, as well as the matriculation examination, in the right order; but there is still apparently no obligation to attend courses of study other than are necessary to pass the examinations. In the case of Switzerland there is no reason to believe that the protective measures have been framed in any way with regard to this country; in a land so largely populated by permanent or temporary visitors from adjacent countries of similar speech some such action may be required if it is desired to retain medical practice in the hands of the Swiss themselves. Probably the temporary difficulty in Italy was of the same nature. Negotiations in regard to reciprocity with Spain have made no progress.

FERTILITY AND STERILITY IN DOMESTIC ANIMALS.

The School of Agriculture, Cambridge, is exhibiting a case in the Agricultural Section of the Government Pavilion at Wembley which should prove of interest to medical men, if not directly, at least from the point of view of comparative physiology. The exhibit consists of a series of photographs, statistical tables, and macroscopic preparations illustrating the work of Mr. J. Hammond, M.A., on Fertility and Sterility in Domestic Animals. Sterility in the male receives a passing reference. The physiology of reproduction in the cow is illustrated by means of an excellent specimen of the reproductive apparatus which brings out all the salient, if familiar, features. There follow sections showing various causes of sterility, whether physiological or pathological. Thus, there are specimens of ovaries of calves before puberty, ovaries of heifers during the œstrual circle, when the corpus luteum has formed; and, in this connexion also, ovaries from which the corpus luteum has been artificially expelled and a premature "heat" period thus induced. For it is believed that the active corpus luteum utilises some substance ("generative ferment") present only in small quantities in the blood, which is necessary for the growth of the follicle, and whose absence prevents the follicle ripening. Pathological ovaries, in which there is a cystic condition, a persistent corpus luteum, or a tuberculous lesion, are also shown. Some further points are brought out in the section dealing with fertility in the sow. It is shown, for instance, that the older sows produce at a heat period more ripe follicles than the younger. Consequently the latter have on the average smaller litters. This is ascribed to the fact that young growing animals have not so much "generative ferment" available for the ovaries. Atrophy of young embryos is illustrated, and it is concluded that, whatever the cause, this condition is not due to overcrowding in the uterus. The further suggestive point is made that, in the rabbit, the time of year and the factor of domestication play a part. Under Fertility in the Rabbit the series of cross-sections of uteri of suckling and non-suckling rabbits at four-day intervals after parturition is of great interest from the comparative point of view. It is suggested that the atrophy of the uterus is probably brought about by the mammary glands utilising "generative ferment" which is necessary for the activity of the ovaries; for the follicles and corpora lutea become atrophic and the ovarian secretion necessary for the nutrition of the uterus is not produced. These effects may be counteracted by allowing the doe to suckle only a few young, or by feeding heavily with oats and juicy green food. Altogether the exhibit well repays the close scrutiny which is necessary for a clear understanding of its significance.

The Crown authorities have appointed Mr. Archibald Young, B.Sc, M.B., C.M., F.R.F.P.S. Glasg., to the Regius Chair of Surgery in Glasgow University, in succession to the late Sir William Macewen.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXV.—THE TREATMENT OF MARASMUS IN INFANTS.

The basal metabolism of the infant has been found to fall outside the limits of the normal when the child has lost one-fifth of its body-weight. A child therefore can be considered as marasmic if its weight is less than four-fifths of the expected weight for its age. Marasmus may be primary, a "vice of nutrition" only; or secondary to some other disease. The patient may have recovered from the original disease; if not, then treatment must be directed to it as well as to the marasmus. Disorders of digestion are not infrequent, but many cases run their course without any digestive disturbance. In the treatment of marasmus breast-milk should be given whenever available, even if partial breast-feeding only is possible. In the absence of breast-feeding the best results are obtained by using modifications of cows' milk. Having started feeding with such a mixture, it is important to continue with this form of food for a considerable time, for frequent changes in the kind and composition of the food lead but to disappointment or disaster. Not infrequently the regularisation of the time of feeding and strict attention to detail will produce improvement in an atrophic child who has previously not improved on a diet with which no fault could reasonably be found. Marasmic children are very susceptible to cold, and many have a subnormal temperature; the supplying of artificial warmth is therefore very important.

The marasmic baby should be given more food than a normal baby of the same weight. It should be the rule to feed by the expected weight for its age rather than by actual weight, or if the caloric system is used, to give the child about 70 calories per pound per diem. The total calories of a milk mixture can easily be calculated if it be remembered that 1 oz. of milk (4 per cent. fat) has a caloric value of 20, and 1 oz. of sugar a caloric value of 120. When treatment is first instituted many babies will not take this amount of food, but after a time they will usually do so, and many will take even larger amounts. It is advisable to use one of the less fermentable sugars because of the tendency towards carbohydrate indigestion. Therefore dextrimaltose (Mead's preparation is a useful one) should be used in preference to lactose or cane sugar. The caloric value of a feed may be increased by the addition of carbohydrate in this form, which, in the absence of diarrhœa, is well absorbed. The amount used can be 5 to 10 per cent. Additional cream may be used to bring up the caloric value of the food, but is unnecessary because the amount of cream in an ordinary good milk is sufficient for the needs of the child. The marasmic child is able to digest that amount of fat as well as the normal child. The marked cases of fat indigestion described by German writers are rare in this country. If a dried milk be preferred to fresh milk, a half-cream variety should be used, since the fat absorption is better than with the full-cream variety.

Digestive Disturbances.

Marasmus may be complicated by digestive disturbances, and although many of the varieties are not quite sharply defined, mixed forms occurring in many instances, and even one form supervening on another, yet they can be roughly classified thus: (1) Fat indigestion; (2) carbohydrate indigestion; (3) protein indigestion; (4) pylorospasm; and (5) diarrhœa and vomiting.

Fat Indigestion.—This occurs chiefly under two conditions—(*a*) if diarrhœa develops; (*b*) if high fat content dried milks are used. In the latter group the fat indigestion is recognised by the passage of large pale soap stools. Unless the soap stool is a bulky one fat indigestion does not occur. The form of fat indigestion described by German workers may be included in this group. In the cases showing diarrhœa, particularly if this is severe and of sudden onset, a preliminary period of starvation, during which the child is given water, tea, or albumin water freely, and lasting 6 to 12 hours, is advisable. In many cases, however, the child is too feeble to submit to this form of treatment. If the child is dehydrated, normal saline should be given by rectum or subcutaneously. The dietary should be a low fat one, and the carbohydrate given should be in the form of dextrimaltose. The low fat dietary can be obtained by giving skimmed milk in place of whole milk. The milk should be machine-skimmed, or one of the dried skimmed milks may be used. Horlick's malted milk, diluted 1 in 8, gives a mixture which is very useful in the treatment of diarrhœa, and containing a low fat percentage. Sweetened condensed milk in the same or greater dilutions also proves useful in some cases, for it also has a low fat and a high carbohydrate content; its use, however, is limited because in many cases the sugar increases the tendency to diarrhœa. One other form of feeding is sometimes useful as a temporary measure—i.e., the giving of protein milk. This method of feeding is described under carbohydrate indigestion. The low fat mixture can be continued for a considerable period, but an attempt should be made to increase the amount of fat as soon as possible, because of the danger of vitamin A starvation and of abnormal calcium metabolism. The treatment of the second group of indigestion consists either in substituting for the dried milk a half-cream variety of the same brand or an ordinary milk mixture. It is rarely necessary to give the very low fat mixture described in the first group.

Carbohydrate Indigestion.—This is the most frequent form of indigestion. The stools are acid, loose, and green, and may show mucus and soap curds; vomiting and colic are frequent, and the child develops sore buttocks; diarrhœa is very liable to occur. These cases arise most frequently on artificial foods or where lactose or cane sugar are used as the sweetening agents. Most of these children improve when a normal milk mixture, sweetened with dextrimaltose, is used, but it may be necessary to omit all added sugar before the symptoms clear up completely. If diarrhœa occurs the methods outlined under fat indigestion should be used. It is in this form of diarrhœa (fermentative diarrhœa) that the best results are obtained from protein milk, and this form of feeding will frequently clear up cases that have resisted all other forms of treatment. Protein milk may be easily prepared by the addition of calcium caseinate, sold under the name of "Casec" by Mead Johnson and Co. For children over 3 months of age 20 gr. of this powder can be added to every ounce of milk. This method of feeding is, however, a temporary expedient, since many children after improving and gaining weight fail to show satisfactory progress and may even develop protein indigestion.

Protein Indigestion.—Fortunately this is the rarest form of indigestion, since it is necessary to give all artificially-fed babies a greater amount of protein than breast-fed babies, due probably to the different amino-acid contents between cows' milk and human milk. Protein indigestion only occurs where an excess of protein is present in the food over a long period. It is shown by the presence in the stool of large hard brownish curds, very different in consistence and appearance from the soft white smaller curds of neutral fat or soap, and which previously were regarded as evidence of protein indigestion. The treatment of protein indigestion is the giving of milk mixtures in the ordinary dilutions and without the addition of extra protein; the addition of 1, 2, or 3 gr. of sodium citrate to the ounce of milk is also helpful.

Pylorospasm.—This is a group of cases important to recognise, because treatment is often very successful. Vomiting is frequent, often severe; constipation or diarrhœa may be present, also anorexia and wasting. On examination gastric peristalsis may be seen, rarely marked in degree; a pyloric tumour is not palpable. Efficient X ray examination will establish the diagnosis. The treatment most likely to be successful is daily lavage of the stomach with 1 per cent. bicarbonate of soda solution, and the giving of an ordinary milk mixture. Citration of the latter is often very helpful. In certain cases the addition of ½ gr. of bicarbonate of soda to the ounce of milk initiates an improvement. If these methods are unsuccessful the effect of atropine may be tried. The solution of atropine sulphate should be made up freshly every two or three days, the strength of the solution being ½ gr. of atropine sulphate in 1 oz. of distilled water—i.e., each minim contains 1/960 gr. The initial dose is 1 minim given 15 minutes before each feed; this can be increased to 2 or 3 minims if symptoms continue and if no sign of overdosage with atropine is observed. The signs of overdosage are flushing and intestinal distension.

Vitamins.—The vitamin content of the diet is of great importance both in the production of marasmus and in its treatment. Absence of fat in the food—e.g., the use of machine-skimmed condensed milk—will produce atrophy, and it is essential in treating marasmus to give an adequate supply of fat in the food to ensure the presence of vitamin A and of the calcium depositing (anti-rachitic) vitamin. Some dried humanised milks have a relatively poor calcium content and are not suitable for prolonged use in marasmus, even if the vitamin content is satisfactory. The amount of calcium in ordinary cows' milk, although variable, is sufficient for the needs of the child.

Fruit juice should be given daily to marasmic infants, since a certain number of cases fail to make satisfactory progress until this is done. The same remark is true of vitamin B, an adequate supply of which can be ensured by adding 1 drachm of marmite to the 24 hours' supply of milk.

Acid Milk.

The use of "acid milk" has certain advantages in the treatment of marasmic infants over 3 months of age. The buffer value of cows' milk is high—i.e., it contains a considerable amount of substances capable of combining with acid without undergoing a change in reaction. Pepsin can only act at a certain degree of acidity, and to produce that acidity in cows' milk requires the addition of three to six times the amount of acid required to bring breast-milk to the same degree of acidity. Cows' milk, therefore, involves a greater task on the part of the child's stomach than breast-milk. The buffer can be neutralised in several ways—(1) by extreme dilution; (2) by drying milk; (3) by the addition of acid; hydrochloric, citric, and lactic acids have been used. Hydrochloric acid milk is prepared by the addition of 2 drachms of decinormal hydrochloric acid and 2 drachms of water to every ounce of milk. The acid should be added to the milk, and not vice versa, or clotting will occur; clotting may also occur if the milk is not fresh or is made too hot. Citric acid milk is prepared by the addition of ½ g. of citric acid to each ounce of milk, to this mixture is added an equal quantity of water. Milk prepared in this way has almost the same hydrogen-ion concentration as breast-milk.

Assistant Physician, Birmingham General Hospital;
Lecturer on Infant Hygiene and Diseases of Children,
University of Birmingham.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

(Continued from p. 353.)

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, JULY 23RD.

THIS section met on three days at the Technical College, Bradford, Dr. JOHN S. FAIRBAIRN (London), President of the section, occupying the chair. Dr. J. ABERNETHY WILLETT (London) opened a discussion at the first meeting on the

Methods of the Antenatal Clinic and their Application to Private Practice.

Dr. Willett said that he proposed to take as a basis the methods and results of a year's (1923) practice in the antenatal department of the City of London Maternity Hospital and to consider how far they might be applied to private practice, confining his remarks to the clinical aspect of the subject. His personal experience of non-supervised pregnancy was small, the results of omission being exemplified by the emergency admissions, for at the clinic routine examination was made in all primigravidæ and all multiparæ with a history of any abnormality. There were, he said, two definite phases or periods in antenatal work: the first from conception to viability of the fœtus, which was concerned with preservation of pregnancy and the health of the mother; the second from viability onwards, when the aim was that of obviating untoward developments during labour.

First Phase: From Conception to Viability of Child.

Owing to lack of sufficient material he did not propose to enter into detail upon the preventive aspects during this phase, as by the rules of the City of London Maternity Hospital patients were not usually seen until the twenty-eighth week. He felt sure that later speakers, especially those in private practice, would be able to tell the section what proportion of patients sought their advice during pregnancy, what were the more common ailments, and how best they were treated. He emphasised the value of seeing patients early in this first phase, the accomplishment of which meant educating and explaining to mothers the value of antenatal methods. He referred to the importance of obtaining the medical history, the routine examination of heart, lungs, and urine, and also a few hints on personal hygiene—such as modification of diet, the ingestion of plenty of fluid, and care of the breasts; and finally, that patients be warned to report anything abnormal. He then proceeded to discuss some of the more important major complications of early pregnancy, including vomiting, abortion, tuberculosis, morbus cordis, and venereal disease.

Complications of the Second Phase.

The number of patients examined was 2145, and of these 204 were found to have some abnormality which required treatment or investigation, which were grouped as follows: (1) Albuminuria: The most frequent abnormality, occurring in 57 cases, or 27·9 per cent. of cases requiring treatment; of these only 4 were admitted as in-patients; in no case did eclampsia develop. (2) Pyelitis of pregnancy: Rare; 0·4 per cent. as determined by bacteriological examination. (3) Abnormal presentation: One shoulder and two face presentations; not recognised by antenatal examination; probably developed at onset of labour. (4) Breech presentations: Probably occurred more commonly than was usually thought. Diagnosis usually easy, except under certain circumstances, when X rays might prove helpful. He advocated external version. (5) Misfits: The cardinal sign of this group was unduly high situation of the fœtal head; there were 24 instances. These were mostly in patients with a pelvis described as "under average." The occipito-posterior was another cause. (6) Occipito-posterior position: No treatment was advised if the head was deeply engaged, but if the head was high he recommended the "Buist" method of rotation.

Examination and Treatment.

The speaker emphasised the importance of noting the shape of pelvis and gave an easy and satisfactory method of doing this without the aid of callipers. He then explained his method of palpating the head by abdominal examination, using the palm of his hand and finger-tips. It was essential to push the head down in the axis of the brim, to note the relationship of the parietal eminence to the pubes, and also the antero-posterior thickness of the latter. He was in the habit of teaching that a palpable parietal was to be regarded as a warning during pregnancy and a danger signal in labour. He hesitated to say much about vaginal examinations in these cases, but in his opinion they should be regarded as confirmatory, and unless the head had engaged very little information would be obtained. He personally relied more and more on results obtained by abdominal examination. He realised that there must be two schools of thought as to the correct treatment of abnormal cases: he personally favoured the induction method as more nearly approaching the physiological ideal. He said that induction of labour was practised for the high position of the head in 24 instances—5 approximately at full time and 19 varying at dates from 36 weeks onwards. There was no maternal mortality, but one infant stillborn. Forceps were needed on one occasion only. Cæsarean section for cases with grosser deformities of the pelvis or for bad obstetric histories was performed on 13 cases, all of which recovered.

Labour was induced on 16 occasions for post-maturity with no maternal or fœtal mortality. Owing to the uncertainty of dates he adopted the general rule of inducing 300 days after the last reputed period.

The routine in cases of ante-partum hæmorrhage was to admit all the severe cases and the others were advised to rest at home and to return at once if hæmorrhage recurred. He found that examination before dilatation disclosed very little, and he sometimes thought that treatment after the thirty-sixth week should be active dilatation under anæsthesia to admit one finger inside the uterus.

Dr. Willett then drew attention to the three common types of emergency admission resulting from non-supervised pregnancy and illustrated them by actual examples. Antenatal supervision was not only for the patient's interest, but also for the peace of mind of the doctor, for much of the unpopularity of midwifery was due to its uncertainty, and antenatal work should remove much of this. It should also prevent or minimise the complications of pregnancy and labour, and by reducing operative interference there should be a corresponding fall in septic puerperal mortality and morbidity rate.

Dr. RHODA ADAMSON (Leeds) gave her experience of a large prematernity clinic instituted in connexion with the Ministry of Munitions during the war. She was a strong supporter of antenatal supervision and especially advocated the investigation of vaginal discharges during pregnancy, and also a Wassermann reaction being performed. In all suspicious cases, even though the Wassermann was negative, she advised the carrying out of thorough anti-syphilitic treatment.

Dr. ENEAS K. MACKENZIE (Tain, N.B.) gave an interesting account of antenatal methods as carried out by him in a rural practice in the Scottish Highlands. This practice was situated in the Easter Ross district and involved an average of 3700 visits and 2400 consultations per annum, and this meant over 11,000 miles travelling. Since 1915 his average number of confinements per annum was 77, and of these 33 per cent. were primiparæ. The practice was typically rural, the patients were mostly fisherfolk and crofters who lived in one or two-roomed cottages without any conveniences. The difficulties of distance and locomotion were great and the question he had to answer was: "Could he, single-handed, devote the necessary time and care as to satisfy the ideals upon which this paper was based?" He unhesitatingly answered in the affirmative; not only so, but he found that antenatal care and the knowledge which it gave, not only removed the anxieties of his practice in these cases, but simplified his procedure, and in the end made his actual work less. He then gave the details of his methods of antenatal care. He had attended 680 confinements since 1915, of which 224 were primiparæ. There were only 11 stillbirths, and no cases of puerperal fever. The maternity mortality was nil. Forceps were used in 212 cases. In the early days of his practice he had met with opposition, especially at the hands of the old "howdie," or handywoman, but this had been soon overcome.

Major **Edward Moss**, R.A.M.C., gave the result of four years' practice, from 1920 to 1923 inclusive, at the Louise Margaret Hospital, Aldershot. Of 1850 women who were confined all of them had had antenatal supervision and there was only one death; the forceps-rate was 7 per cent. He considered it most important to recognise the early symptoms of pregnancy toxæmias and to admit these cases to hospital for preventive treatment. During this period he had had four cases of eclampsia. It was interesting to note that of these cases three occurred during the first year, one in the second year, and none during the third and fourth years. He believed this to be due to more efficient antenatal treatment. In his concluding remarks he made a strong plea for universal antenatal supervision with the provision of specially equipped maternity hospitals for the poorer classes.

Discussion.

Dr. R. W. **Johnstone** (Edinburgh) referred to the pioneer work of the late Dr. J. W. Ballantyne, of Edinburgh, in this connexion. The older obstetricians were inclined to think that antenatal observation meant merely testing of the urine and the examination of the pelvis, but the more antenatal care was practised, the more obvious it had become that there were many other conditions to be attended to. He gave a short résumé of the work of the antenatal department in the Royal Maternity Hospital, Edinburgh, in the year 1923-24, during which time many cases of pyelitis, hyperemesis, cardiac and pulmonary disease had been admitted to the antenatal department, in addition to a large number of albuminurias. Of 58 cases of albuminuria, including pre-eclamptics, admitted for treatment only one had actually developed into eclamptic fits, although several others had had labour induced as a prophylactic measure. With regard to the question of disproportion between the head and the pelvis, he thought that Mr. Willett had treated pelvimetry rather cavalierly, and he was inclined to deprecate the rough-and-ready methods of estimations which the opener of the discussion advocated. He advised a vaginal examination in all cases, as thereby one could rapidly estimate the diagonal conjugate, ascertain by Munro Kerr's method exactly how the head entered the pelvis, and at the same time exclude any abnormal conditions in regard to the soft tissues. In minor cases of disproportion induction of labour was practised, and he drew attention to the value of the pituitrin method as particularly applicable to private practice. His method was to begin by sensitising the uterus with several doses of 5 gr. of quinine in solution, then 1 oz. of castor oil was given, and an injection of pituitary extract commenced some two hours after the castor oil had acted. The pituitary extract was injected in 0·5 c.cm. doses at intervals of 20 minutes to half an hour, until either the patient had had six such doses or pains had begun. If no pains eventuated the course of pituitary extract was repeated 24 hours later, and a second failure was followed by recourse to induction by bougies. The drug method was reasonably successful—no method of induction of labour being uniformly so—and had the advantage that it obviated anything in the nature of manual interference. In closing, Dr. Johnstone referred to the report of the Scottish Commission on Puerperal Morbidity, one of whose recommendations was to the effect that the Insurance Act should be so altered that maternity benefit should be refused to women whose domestic circumstances were such as to make it desirable that they should not be confined at home, and yet who refused to go into hospital. If fever cases were compelled to go into hospital in the interests of the public, surely women in such circumstances should be forced to go into a maternity hospital for their confinements in the interests of the State.

Mr. **Aleck Bourne** (London) said that in his experience ante-partum hæmorrhage, not of the slight menstrual type but more of the "gushing" variety, which was associated with a non-engaged head or a breech presentation, was a symptom of placenta prævia and should be treated as such. On the other hand, if the head was well engaged and this was combined with a trace of albumin, the case should be treated as one of accidental hæmorrhage. In contradistinction to Dr. Willett he was an enthusiast for callipers, as they were easy and accurate in use. He did not think that the intercristal and interspinous diameters were of much value except in grossly abnormal cases, and he relied more on the external conjugate. Mr. Bourne also wished to disagree with the opener on the question of vaginal examinations which, in his opinion, should be made on all primiparæ. As regards contraction of the pelvic outlet, he was convinced it was a definite entity and quoted a recent case in support of this contention.

Dr. F. **Edge** (Birmingham) referred to the danger of the work of antenatal clinics being carried out by people who had not received a thorough training in this important branch.

Dame **Janet Campbell** (Ministry of Health) thought that, with the majority of practitioners in this country, antenatal care was more the exception than the rule. She said that over 500 antenatal clinics had been established, most of them in conjunction with an infant welfare centre. She was strongly in favour of these clinics being conducted by people with special knowledge of the subject The speaker supported Dr. Willett's suggestion in reference to the treatment of ante-partum hæmorrhage.

Several other speakers also took part in the discussion.

The **President**, after emphasising the importance of antenatal work, said that to his mind the main interest of to-day's discussion lay in the unanimity of all the speakers in favour of antenatal supervision; whereas, at a similar meeting at Portsmouth 12 months ago the majority were against it owing to the difficulties of conducting this work in practice. In referring to the controversial subject of the "pelvic outlet" he was of the opinion that these cases did occur, and he was sure that anyone who had experienced such a case as Mr. Bourne described would be convinced of its existence. As regards ante-partum hæmorrhage, he thought Dr. Willett's procedure might be suitable for cases in outlying districts where no suitable hospital accommodation was present.

Dr. **Willett** briefly replied to the various points raised in the discussion.

THURSDAY, JULY 24TH.

On the second day Prof. B. P. **Watson** (Edinburgh) read a paper on

Imperfect Urinary Control following Childbirth and its Surgical Treatment.

The speaker drew attention to the fact that there were a very considerable number of women who under some physical exertion were unable to hold their water. Out of a series of 63 cases of cystocele operated upon by him at the Toronto General Hospital, this complaint was only mentioned in 19 histories. He, however, had sent out a questionnaire 18 months ago and it was found that an additional 22 had suffered from this trouble prior to operation, making a total of 41. In 21 of his private cases 18 had incontinence of urine, and in 99 cases operated upon at the Royal Infirmary, Edinburgh, during the last 18 months 61 were found to be suffering from lack of control. Thus in a total of 183 cases of cystocele, incontinence of urine was present in 120, or 66·1 per cent.; but he believed the percentage was considerably higher as a number of the patients did not reply to his questionnaire. The speaker attributed the condition to sagging of the neck of the bladder away from its normal attachment behind the pubis. The sphincter was not interfered with, but had merely lost its "point d'appui." In his opinion the condition was due to a weakening of the musculo-fascial pubocervical layer which normally supported the base and neck of the bladder. The anatomy of this layer, composed mostly of unstriped muscle, was recently described by Bonney, with whom he was in almost entire agreement.

Although incontinence of urine occasionally occurred in nulliparous women, he was convinced that parturient injuries were the main factor in its causation. During labour, when the fœtal head came down upon the pelvic floor, there was over-stretching, and this was aggravated in a large number of cases by the obstetrician attempting to save the perineum at the expense of the anterior pelvic supports. As a prophylactic measure, he therefore recommended episiotomy in all cases of undue stretching and especially in breech presentations in primiparæ.

Treatment.

Prof. Watson then described a satisfactory operation which was similar to one devised by Eden and Lockyer for cystocele. The vertical incision, however, should reach almost to the urethral meatus, and in addition it was necessary to dissect out the pubocervical layer. Special attention was paid to overlapping the cut ends of this fascia at the base of the bladder by means of Lembert sutures, the top suture being the most important. Catgut was used throughout the operation.

The after-treatment was of the greatest importance, and he recommended the use of a self-retaining catheter for at least five days after the operation, and in some cases ten days. The results of 105 cases operated upon were as follows: (1) Perfect control, 65·7 per cent.; (2) control not perfect but better than before, 21·9 per cent.; (3) no improvement, 12·4 per cent. The paper was illustrated by lantern slides and drawings.

Discussion.

Dr. R. W. JOHNSTONE said that to isolate the pubocervical fascial layer which Prof. Watson had described was a much easier thing than description would perhaps lead one to think. Along with most gynæcologists, the speaker had usually been content to tighten up the neck of the bladder by means of a purse-string suture, but he was inclined to think that the technique which had been described was more anatomically correct, and ought to lead to more uniform success in the treatment of the imperfect urinary control. He entirely agreed with Prof. Watson as to the prophylactic value of episiotomy, particularly in primiparous breech cases, where the perineum would otherwise have been torn. An episiotomy incision obviated a great deal of difficulty in many cases and enabled a much more accurate coaptation of the cut edges to be made than in a ragged tear, with, as a consequence, a cleaner and stronger healing.

The CHAIRMAN, in thanking Prof. Watson for his paper, said that the condition was frequently met with in practice but sadly neglected in text-books. Prof. Watson had worked the ætiology out on scientific lines and had shown how restoration of the pubocervical musculo-fascial layer would, in a considerable number of cases, cure the condition.

Prof. MILES PHILLIPS (Sheffield), while expressing entire agreement with Prof. Watson, said he understood the experience at Manchester was that the majority of patients with cystocele did not suffer from urinary incontinence. He also concurred with Prof. Watson in advocating prophylactic episiotomy in primiparæ.

Mr. JAMES PHILLIPS (Bradford) read a paper on

Investigation, Pathology, and Treatment of Uterine Bleeding.

He said that the points he wished to emphasise were the following: (1) In some 25 per cent. of cases the bleeding was associated with malignant disease; (2) the whole of the patient's symptoms and disability should be elicited; (3) the goal of treatment should be as complete restoration as possible to functional normality. As regards pathology, of 292 women at or after the fortieth year treated in home or hospital (1919–23) there were 61 cases of malignant disease. The difficulty of diagnosing the earlier cases of cancer was emphasised and cases cited where previous diagnostic curettage had not revealed malignant disease which was subsequently recognised at operation. In investigating a case a full and consecutive history of the patient's illness and symptoms was necessary, and whenever the diagnostic bimanual examination failed to establish the diagnosis, it was urged that the only safe procedure was to have recourse to surgery—either diagnostic or radical. In considering treatment, he was strongly of the opinion, after 24 years of experience, that hysterectomy was, in cases where cancer might be suspected, the only safe procedure, and for a large proportion of the remainder, the only form of treatment likely to restore the patient to normal comfort and health. He had performed this operation in 201 of the 292 cases. Adnexal disease and other causes of pain and tenderness existed in all but 25 of the 201 cases. At the Bradford Royal Infirmary, he stated, radium was not available. The general practitioners, who had the opportunities of seeing the effects of treatment over long periods, were apparently satisfied with the results of hysterectomy and often asked that the surgeon should make a "clean sweep."

Discussion.

Prof. WATSON said that attention should be concentrated on the diagnosis of the cause of the bleeding, and it was important to get a clear history as to whether the type of bleeding was a menorrhagia or a metrorrhagia. In the latter case there were probably associated symptoms such as backache. He recommended a careful bimanual examination under anæsthesia and also diagnostic curettage with thorough examination of all the curettings which should determine whether cancer was present or not. His line of treatment was as follows: (1) If the uterus was not enlarged and no associated disease of the adnexa—radium. (2) Uterus large with associated disease of appendages—hysterectomy. (3) Prolapse of uterus associated with bleeding—Mayo's operation.

Dr. J. J. BELL (Bradford) disagreed with Mr. Phillips, as in his experience a large number of these cases could be cured without radical operation. He had for some time watched the effect of radium and was convinced that cases which did not show gross pathological changes could be controlled and cured by inserting 50 mg. of radium for 10 to 12 hours. Such patients did very well, and felt that they had not lost an important organ. Even if there was any hidden source of cancer cells they would be destroyed by the action of the radium.

The CHAIRMAN agreed with Prof. Watson as to the importance of a thorough investigation. He believed in examination under anæsthesia and preferred to get his gloved finger into the uterine cavity. Should there be no evidence of malignancy or a polypus the case probably came under the category of a chronic metritis, for which radium had proved to be an unqualified success. In cases of malignant disease of the uterus he firmly believed in the use of radium prior to operation.

Dr. GORDON LUKER (London) said he usually advised hysterectomy in all cases where the uterus was enlarged, where there was associated diseases of the adnexa or chronic cervicitis; also if curettings were at all suspicious of malignancy.

Prof. MILES PHILLIPS said that in cases of chronic metritis or subinvolution a dose of 2000 "millicurie" hours would stop all future hæmorrhage. His custom was to make a diagnostic bimanual examination under anæsthesia, having previously obtained permission to perform a hysterectomy if necessary. Should there be no evidence of malignancy or diseased appendages, he in that case inserted radium. He believed that chronic lesions of the cervix were really pre-cancerous.

Prof. MILES PHILLIPS read a paper on the

Advisability of the Routine Pelvic Examination During the Puerperium.

He wished to focus attention on the value of a routine postnatal examination of women. Antenatal work had quite rightly attracted attention, but he had found that very few practitioners made an examination following parturition. He had done so for the past 20 years, and usually performed this examination on the twelfth day of the puerperium. An anæsthetic was not necessary, but the bowels and bladder should be emptied. He advocated not only a careful digital and bimanual examination but also a thorough inspection of the vagina and cervix with the aid of a Sims speculum. Tears in the vagina and cervix were looked for and any granulation tissue or polypi were snipped with scissors and afterwards cauterised with pure carbolic acid. These measures quickly effected a cure. If the cervical canal was patulous and admitted the index finger—normally it should not on the twelfth day—a digital exploration of the uterus was made, followed by intra-uterine irrigation and swabbing. If there was any subinvolution of the pelvic floor or vagina this was noted and treated by longer rest, &c. A retroverted uterus should be replaced and a broad Hodge pessary inserted, which not infrequently effected a permanent cure. He maintained that this routine examination in the puerperium was necessary. All knew that many gynæcological diseases arose from the wear and tear of parturition, and a routine examination in the puerperium was the best method of discovering the early beginnings of these troubles. He laid great stress on the fact that chronic cervicitis was often due to an infection of a lacerated cervix and subsequent formation of granulation tissue and polypi in the angles of the tear; also that endometritis accompanied by defective cervical drainage was probably at the root of many cases of chronic subinvolution.

Dr. R. W. JOHNSTONE said the title of Prof. Phillips's paper had not led him to expect the description of such an elaborate method of examination as the writer appeared to practise. In the Edinburgh Maternity Hospital their practice was to examine all patients before they were discharged, generally about the tenth or twelfth day, but in private practice he preferred to postpone the examination until about the end of the third week. The routine examination involved merely inspection of the perineum, and bimanual examination to detect cervical tears and the position of the uterus. The speculum was never used unless there was some definite indication for it, and he confessed that he felt considerable dubiety as to the wisdom of introducing the finger into the uterine cavity, as Prof. Miles Phillips had described. With regard to retroversion of the uterus, it had been his practice, if he discovered a retroversion at the end of the third week, to leave the condition alone for another three weeks or a month, asking the patient to return at that time. In a large number of cases the displacement was found to have been spontaneously rectified at the end of six weeks, just as had been described in the contribution which the secretary had read. On the other hand, a retroversion was occasionally found to be present in patients at the end of six weeks which was not present at the end of three weeks. Rectification and introduction of a pessary at the end of six weeks still held out good hope of cure as the impetus to involution had not yet exhausted itself.

Prof. WATSON cordially agreed with Prof. Phillips, and said that he looked upon postnatal care as a form of preventive gynæcology. He had found that prolongation of the lochia was often an important symptom of retroversion; this condition often cleared up after replacement of the uterus followed by the insertion of a pessary.

Mr. W. W. KING (Sheffield) read a paper on the

Clinical Manifestations of Pelvic Adenomyoma,

based on his observations in 123 cases upon which he had operated. The growths occurred in the following positions: in the recto-vaginal space in 53 cases, the peritoneum in 26, the ovary in 23, the uterus in 17, and the tube in 4. The growths in the recto-vaginal space involved the rectum more or less extensively in about half the cases, and the utero-sacral ligaments were often infiltrated. The rectum was frequently adherent to the uterus. Peritoneal adenomyomata were characterised by scattered hæmorrhagic cysts; stellate scars upon the peritoneum were often seen and represented healed adenomyomatous implants. The ovarian growths were clinically recognisable by the presence of tar cysts which were frequently of large size, or as pin's head hæmorrhagic cysts upon the surface of the ovary. The uterine tumours of this type simulated unencapsulated fibromyomata. Tubal adenomyomata occurred as localised tumours in the uterine end of the tube. A study of the clinical symptoms showed that 16 per cent. of the cases had no symptoms referable to adenomyoma. In those with symptoms, abdominal pain of "shooting," "griping," or "aching" character was the most frequent complaint. The pain was often associated with vomiting. The other leading symptoms were dysmenorrhœa, rectal pain both at and apart from the periods, menorrhagia, and dyspareunia. The most conclusive physical sign in diagnosis was the presence of a tender retro-cervical ridge with hæmorrhagic cysts projecting into the posterior fornix of the vagina. The utero-sacral ligaments were frequently thickened and tender. An adherent retroversion, with rectal pain upon movement of the uterus, was found to be highly suggestive of adenomyoma. The ultimate results of the operation showed that hysterectomy with removal of the ovaries was the most certain cure, but that less radical operations were often followed by success.

Discussion.

Dr. JOHNSTONE said that he had had relatively a very small experience compared with Dr. King, having operated only on some few cases of adenomyoma of the uterus, as well as a number of cases of so-called chocolate cysts of the ovary. Doubtless he had overlooked many cases in which there were tiny puckered scars of the pelvic peritoneum which Dr. King regarded as of pathological importance. He agreed with Prof. Watson that the most suggestive symptoms were the onset of dysmenorrhœa in later sexual life, combined with menorrhagia, dyspareunia, and in many cases sterility. He would like to ask Mr. King whether he had any idea as to the likelihood of the tiny peritoneal adenomyomata which he had described undergoing spontaneous cure even in the absence of such radical treatment as he was disposed to recommend.

FRIDAY, JULY 25TH.

On the third day Dr. ALICE E. S. CLOW (Cheltenham) opened a discussion on

Dysmenorrhœa in Young Women; Its Incidence, Prevention, and Treatment.

Dr. Clow said that "dysmenorrhœa" was a word to which so many definitions had been given that it was necessary to state in what sense one was using the term. She said that menstruation was a function which, when normal, had no symptoms, and that suffering of any kind associated with this period was abnormal and was included in the term dysmenorrhœa, as used by her. To estimate the incidence of the condition, she had questioned, during the last 11 years, over 2000 healthy girls whose ages ranged from 12 to 22. Of these girls 1830 were at a secondary school and the remaining 220 were students at a training college for teachers. The result was as follows: Number of girls questioned, 2050. Group 1, normal, 78 per cent. Group 2, dysmenorrhœa: slight, 17 per cent.; subacute, 2 per cent.; disabling, 3 per cent.; total, 22 per cent. She had only recorded five cases of "spasmodic" dysmenorrhœa. She drew attention to the fact that her percentage of cases of dysmenorrhœa was much lower than that obtained by the two observers quoted by Blair Bell at the Congress of Obstetrics and Gynæcology last year. The change of school regimen with regard to exercise, and also to the lowering of the age of entrance, had steadily decreased the incidence of dysmenorrhœa. She hoped that it would soon be recognised that it was unnecessary for 22 per cent. of school girls to be subject to a monthly recurrence of pain. The speaker said she had known since her girlhood that normal menstruation was a painless function, and that not only could baths and exercise be continued with impunity throughout the normal period, but that by such a regimen dysmenorrhœa was usually relieved if not dispelled. During her first year of medical inspection at the school which supplied the data for this paper the rule was that games, gymnastics, and baths were discontinued during the first three days of the period. Those who felt inclined were allowed to go out for a walk, the others could lie down and read. In some of the boarding-houses the latter became the popular procedure, which resulted in an increasing number of girls not feeling well enough to continue the ordinary routine of school life. The practice of keeping girls in bed for one or two days during menstruation incurred not only a waste of time, but also was a source of future suffering.

It was her custom to question each girl at puberty as to her feelings and habits at the menstrual period, and having explained her own views advised the girl to put them into practice after consent from home had been obtained. The advice given corresponded to a leaflet issued by the Council of the Medical Schools Association. She then showed a table giving a summary of results obtained at the inquiry at the school and at the training college, and the main facts brought out by these two independent sets of figures were: (1) That the incidence of dysmenorrhœa had been reduced in each case, the reduction, over all, being approximately 75 per cent. (2) That there had been a decrease in the number of those who lay down during the period and a marked increase in the number who had warm baths and took their exercise as usual. (3) That the total incidence of dysmenorrhœa was less amongst the students than in the case of the school girls in spite of the fact that the former were all over the age of 18, when dysmenorrhœa was more common than in earlier girlhood. (4) There was a decrease in the number of cases of constipation. The speaker was sure that the practice of suddenly stopping all activity during the period was responsible for the relatively high proportion of cases of dysmenorrhœa among women of the educated class. She knew of no figures confirming hers in this country, but in America Miss Florence Meredith had recorded similar results. Dr. Clow was convinced that the best method of reducing incidence of this complaint would be to teach every school girl the simple rules of menstrual hygiene, and she suggested that the "Advice Leaflet" quoted above be distributed amongst the girls. It was also necessary to educate the mothers. It was her opinion that if dysmenorrhœa came to be regarded as a disqualifying complaint amongst female workers, many of the cases which could be cured by exercise would disappear and thus the chief source of inefficiency of the unmarried woman worker would be removed. She would like to suggest that schools and factories should provide private lavatory accommodation with facilities for washing, as the chafing caused by wearing the same sanitary towel often led to painful abrasions of the skin; these caused more suffering than the dysmenorrhœa itself.

Treatment.

Dr. Clow held that an operation should not be performed nor even suggested until a course of treatment by baths and exercise, with a judicious administration of drugs, had been tried for at least six months and found useless. Having excluded disease or any structural abnormality by routine examination, she advised the patient to take a hot bath at the commencement of the period and to continue it throughout. This gave relief even after the onset of the pain. Daily exercise should be taken some days before and throughout the period, and in the case of nervous girls it was necessary to prescribe a mild analgesia for the first three periods. It was exceptional to come across a girl whose dysmenorrhœa was not cured or much relieved by these means. The speaker had no collective results of the treatment of the severer cases of dysmenorrhœa among school girls; she had, however, obtained the subsequent histories of 100 consecutive cases of dysmenorrhœa in nulliparous women with no organic disease, who were better after being treated with baths and exercise. The results were as follows: 59 were cured (30 of these had, in addition, some drug treatment); 32 were relieved of pain, but were conscious of some discomfort (of these 22 were helped by drugs); 9 were no better; 6 did not give the treatment a trial; and 3 were relieved after a backward displacement of uterus was rectified. The drug most usually prescribed was ammonal; extracts of the ductless glands were not given unless there was some evidence of disorder of the endocrine system. The type known as "spasmodic dysmenorrhœa" was not so successfully dealt with by the above means; but she had never known a case of this type develop among the school or college girls who had continued their games throughout the period. This would suggest that the prevention of congestion during the early years of menstrual life was prophylactic also against spasmodic dysmenorrhœa. Dr. Clow was inclined to think that if all employers of female labour refused leave of absence for menstrual disability, the extra hardship endured by the few would be well compensated by the benefit conferred on the many.

Dr. MINNIE MADGSHON (London), medical officer, G.P.O., gave her experience of the incidence of dysmenorrhœa among female workers of the institution. She said there were roughly about 10,000 women employed in the Post Office, and although it was difficult to obtain reliable statistics, she estimated that the average time lost through dysmenorrhœa was one and a half days per officer per year; in addition the time spent in the sick-bay through temporary incapacity was two hours per officer per year. The above figures included women of all ages, but since 1911 a total of 2924 girl probationers aged between 14 and 15 years had been admitted to the Post Office. They were all examined on admission; of these 1823 were re-examined two years later and the incidence of dysmenorrhœa noted. It was found that on first examination 95 per cent. had no pain or pain without incapacity; on re-examination the figure was 93 per cent. For those requiring frequent rest the figures were 0·5 and 1 per cent. respectively.

Dr. LEONARD PHILLIPS (London) said he could not altogether agree with Dr. Clow's paper. He had for some time treated his cases on hygienic lines, but was convinced that there was a type of intractable dysmenorrhœa which could not be cured except by hysterectomy or radium. It was important to investigate each case thoroughly and to recognise the clinical type to which it belonged. As a consultant he saw many cases of disabling dysmenorrhœa which were sent to him after other treatment had failed, and he wished that baths and exercises would cure these cases. The best results from treatment were obtained between the ages of 16 and 20; after 30 most cases were intractable. When cases that could be cured by drugs, operative means, and attention to hygiene were excluded there remained the "uncurable" cases. For these he recommended radium, and after cessation of the period the pain disappeared.

Dr. CATHERINE CHISHOLM (Manchester) said that she had adopted Dr. Clow's line of treatment for some years with good results. She believed in routine games and exercises for healthy girls, but pale and anæmic girls who lost profusely at the periods should have their general physical condition improved before undertaking exercises. There was also another group in which fatigue—both physical and mental—increased dysmenorrhœa, and in these cases prophylactic exercises should be ordered with reservation.

Dr. RHODA ADAMSON gave her experience of cases which were drawn from (1) private practice, (2) students, and (3) 4000 women who were engaged at engineering works during the war. The first two classes came under the heading of those who led an unhygienic type of life, and most of these cases were improved by baths, exercise, and attention to the bowels; the others could be cured by diathermy, and she entirely disagreed with Dr. Phillips that any cases were incurable. She had no records of the third class, but practically none of these women suffered from dysmenorrhœa, except those who were sitting down all day. When heavier work was substituted the pain immediately disappeared. In conclusion, she said she would like to congratulate Dr. Clow on the reasonable treatment she advocated.

Mr. BOURNE said he thought the work of medical women most valuable, especially with regard to their investigations into the incidence of dysmenorrhœa. It was only since they had studied this subject that we had any clear conception of this important point. As a gynæcologist, however, he was convinced there was a pathological type which was represented in Dr. Clow's table by the 3 per cent. suffering from disabling dysmenorrhœa. He was in favour of the propaganda advocated by Dr. Clow for the 97 per cent., but wanted to know how to cure the remaining 3 per cent. He emphatically disagreed with Dr. Rhoda Adamson, who did not believe that any case was incurable.

Dr. W. A. POTTS (Birmingham) asked if Dr. Clow made any rules about sea-bathing; also if she found the mentality, as expressed in fits of bad temper, &c., was affected by menstruation. In those cases where hygiene and physical treatment failed he would like to put in a plea for psychological treatment carried out by a psychologist and continued for a sufficient length of time. All necessary physical treatment should be carried out first, he said, but when that had been done it should be realised what a serious step it was to operate where pain was the only symptom.

Sir MALCOLM WATSON (Klang, F.M.S.) said that he practised in the Malay States, where the average daily temperature was 90° F., and had found that in these regions the men who took plenty of exercise were the fittest. He had therefore decided, since hearing Dr. Clow's paper, to recommend baths and exercises for the treatment of dysmenorrhœa amongst the European women out there.

Several other speakers took part in the discussion.

The PRESIDENT, after congratulating the meeting on the excellence of the discussion, thanked the various women doctors for their valuable contributions of data obtained from schools, training colleges, and other institutions, and said that it was only by this means one was able to get a comparison with the normal, as the majority of cases seen by gynæcologists were abnormal.

Dr. CLOW, replying briefly, stated that she had never known any harm result from girls taking cold baths during menstruation. She could not definitely say whether the mentality was affected, but housemistresses had noticed that some girls were occasionally depressed at this time.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 23RD.

THIS section met on three days, with Dr. THOMAS GRAINGER STEWART, the President, in the chair. The first day of meeting was devoted to a discussion on

Certification in Mental Disorders from the Medical and Social Aspects.

The PRESIDENT, in his introductory address, said that the officers of the section had endeavoured to choose for discussion subjects of interest to the general practitioner as well as to the specialist. Recently the process of certification in mental disorders had been widely commented upon in the lay press and, he feared, had been somewhat misrepresented; in this matter the laity had an erroneous idea as to the exact function fulfilled by the medical practitioner. The question before the practitioner's mind should invariably be "What is best for the patient?" If certification as at present carried out was not the best that could be done, what alternatives could be devised?

The opening paper of the discussion was then read by Dr. H. YELLOWLEES (The Retreat, York), who began by pointing out that the statutory certificate dealt essentially with the patient's social relations rather than with his medical state, and was primarily concerned with his fitness "to be taken charge of and detained" and not with his unsoundness of mind. The fact that the Lunacy Act was only interested in mental disease if and when it rendered a patient fit for detention had an all-important bearing on the course the practitioner must adopt when writing a certificate. The word "detention" signified an interference with personal liberty; no consideration was given to the fact that an appreciable number of certified patients were not only willing but anxious to stay under care and treatment. Lunacy legislation was so obsessed with the idea of safeguarding personal liberty that it ignored almost completely the facts that the insane were ill, that their illness often prevented their knowing what was best for them, and that the opinion most likely to be of value on the point was that of a competent medical man. Dr. Yellowlees then proceeded to comment upon the process of presenting the petition and the signing of the reception order. In his opinion, the latter was the weakest part of the system of certification. Many specially appointed justices of the peace and magistrates—as distinct from county court judges—although actuated by a sincere desire for the public good, were often ignorant of the detailed requirements of the lunacy law. Several instances of mistakes resulting from such lack of knowledge were cited. As regards the certificate from the certifying physician's standpoint, the law was not satisfied with a mere statement of his conclusions; it insisted that he should set forth the "facts indicating insanity." The physician, therefore, was not made the sole judge of the patient's insanity; he placed the observed facts on which his opinion rested before the representative of the law, who had every right to draw a different conclusion from them if he felt so disposed.

Dr. Yellowlees contrasted the procedure of certification in England with that obtaining in Scotland; under the law of the latter the petition and the certificates were laid before the sheriff, a trained legal official, who issued the order for the patient's detention. This is one of the explanations of the comparative immunity from legal trouble in mental work in Scotland. Concerning borderland cases, Dr. Yellowlees feared that the public was being misled on the subject. Generally speaking, a true borderland case did not become insane, a mild or incipient case was by no means necessarily a curable one, and the acute, recent, recoverable cases were, on the whole, far more abnormal in conduct and required far more specially skilled care than the permanently and hopelessly insane. Unfortunately, the opposite view was held by and was being taught to the general public.

Discussion.

Dr. G. W. B. James (Moorcroft House, Hillingdon) suggested clinical points which might usefully be borne in mind when certification was in question. First, an important consideration was the degree of insight the patient had into his own condition. Did he realise he was ill? With a fair degree of insight it might be possible to avoid certification in a private patient and have him admitted to a mental hospital as a voluntary boarder. Secondly, the question of suicidal impulses arose. When a patient showed evidence of being actively suicidal certification was the wisest course. At the same time, however, Dr. James believed it impossible as a general rule to certify a patient who intended to commit suicide unless there was other evidence of mental disorder. Thirdly, there was the question of danger to others. Ideas of persecution were danger-signals. Many men lived harmless lives with vague ideas of persecution, but the patient who disclosed a firmly crystallised belief that he was being persecuted by a specific individual was a danger. Marital suspicions occurring in chronic alcoholics and senile disorders were also a certain menace to the safety of the family and the public. Dr. James then dealt with the surprising paradox that a patient duly certified could legally refuse the treatment considered necessary; a case of meningo-vascular cerebral syphilis—with a good prognosis from energetic anti-syphilitic treatment—was mentioned as an example.

Dr. J. H. Thornley (Scarborough) spoke from the standpoint of the general practitioner. He considered that more onus was thrust upon the practitioner than was justified, and entered a plea for the appointment of a State mental expert to sign and endorse certificates supporting the medical opinion that a particular patient was of unsound mind. Such a mental expert should also be available for consultation in the same way as the medical officer of health gave an opinion in the case of infectious disease. Dr. Thornley also advocated a form of temporary "detention" for mild and borderland cases.

Dr. Stanford Read (London) differentiated between "insanity" and "unsoundness of mind," the former being a legal term involving the necessity for control. In certification the facts indicating insanity were highly debatable, and without a knowledge of psychopathology a medical man might commit a patient in whose case no such step was required. Thus, symptoms such as depression or suicidal ideas might be taken at an incorrect value. He agreed with Dr. Thornley that it would be ideal in every local area to have an expert in mental diseases who would be either responsible for certification or be a co-signatory with the medical practitioner. The stigma attached to insanity was deeply rooted and was only increased by medical men speaking of "nervous breakdown" when the word "mental" should be used. The public should be educated in and familiarised with all the factors of mental hygiene; this was the only way in which the stigma could gradually be removed. Dr. Stanford Read instanced the town of Gheel, in Belgium, where over a thousand certified patients are housed with the population, a system that has been in force for hundreds of years. As a result, there has developed in this town such familiarity with insanity that it is viewed in a light very different from the usual, and the stigma has sunk into insignificance.

Dr. J. I. Russell (North Riding Mental Hospital) said that by our present tendency to advise the institution of treatment centres for mental disorders in general hospitals—situated in traffic and without verandahs, gardens, &c.—we encouraged the prejudice against mental hospitals. We should rather do all in our power to elevate the mental hospital and to advocate a modified form of certification; patients would then be received earlier and the suicide of many incipient cases prevented. He considered that the same procedure of certification should apply to private and rate-aided patients alike, and that the relative of the latter should have the same rights as the petitioner in the case of private patients.

Dr. Bedford Pierce (Leeds) urged the facilitation in every possible way of the treatment of patients as voluntary boarders; the system should also apply in public mental hospitals. He supported the plea for temporary detention without certification in recent acute cases, and advocated the appointment of a legal referee in each district empowered to call in expert advice in difficult cases. The responsibility of initiating treatment should lie with the medical practitioner, but, at the same time, he should be given effective protection; the patient, however, should have the right, if aggrieved, to appeal to the legal referee.

Dr. J. Mills (Galway) expressed his agreement with the chief points in the reforms suggested by Dr. Bedford Pierce. He added that, in his opinion, the most urgent reform was needed in the regulations governing the so-called "pauper" patients; this class should be admissible to district mental hospitals on the same conditions as voluntary boarders were admitted to private institutions. Dr. Mills recalled instances of such cases suffering from incipient insanity coming to him to ask for admission to the mental hospital; under the law he was forced to refuse. He also suggested that a form of temporary detention on the certificate of a specially appointed medical referee would assist in giving confidence in mental hospitals to the general public.

Dr. Hildred Carlill (London) mentioned the difficulty experienced in stating the "facts observed indicating insanity" in some cases of mental disorder, and gave an instance.

Dr. D. Blair (Lancaster) said that it was unfair to the family physician to have the whole onus of certification thrust upon him; he considered that every patient should be certified by two medical men—one a specially appointed expert in mental disorder and the other the patient's usual medical attendant.

Dr. C. Worster-Drought (London) dealt further with the fact that a patient certified as of unsound mind can still legally refuse treatment; this fact was not generally known, but was of particular importance in the case of the treatment of cases of neurosyphilis by intravenous or intrathecal injection, of G.P.I. by malarial infection, and even for the performance of lumbar puncture. Consequently certification as of unsound mind did not imply compulsory treatment. He also mentioned the difficult question of the advisability of certifying solely on definite suicidal impulses, and cited instances. A further plea was entered for the treatment of mild or early cases of mental disorder occurring in those who were unable to afford a private mental hospital either as voluntary boarders in public mental hospitals or in special institutions; it was pointed out as a defect in our social system that there was no institution between the general hospital and county asylum for the reception of such cases. Dr. Worster-Drought also drew attention to the fact that often in the actual practice of Section 13 of the Lunacy Act the relieving officer's opinion of the patient's mental state is the most important factor.

Thursday, July 24th.

On the second day the proceedings were devoted to a discussion on the

Nature and Treatment of Epilepsy.

Dr. James Collier (London), in opening the discussion, stated that investigations during recent years had brought no great discoveries fundamentally to alter our view concerning the nature and treatment of epilepsy; nevertheless, some progress had been made towards creating a wider conception of the disease and the bringing into line of those conditions in which the manifestations resembled or were identical with those of the malady which we termed "idiopathic epilepsy." There had also been some useful work done in the separation of certain clinical types of epilepsy—pyknolepsy, myoclonus epilepsy, affect epilepsy—and also at least one valuable addition to our therapeutic measures for its treatment. As regards the nature of epilepsy, Dr. Collier considered that it was not in any sense a disease of the brain, but that there was much evidence in favour of its resulting from a form of metabolic disturbance. He also cited other conditions of known metabolic dyscrasia in which epileptiform convulsions occurred —e.g., uræmia and eclampsia—while in his opinion infantile convulsions were epileptic in nature and were similarly produced. Among the points in favour of a metabolic disturbance were the periodicity of the attacks, the resemblance of status epilepticus to an acute toxic process, the immunity of the epileptics from so many common diseases, the constant leucocytosis with increase at the time of the paroxysm, the diminished blood alkalinity both before and after the attack, and the presence of choline in the cerebrospinal fluid of some epileptics. There was very little evidence in favour of an endocrine disturbance as responsible for the manifestations of epilepsy, while in his experience protein therapy—on the ground that the cause of the seizure was "anaphylactic shock"—did not yield any convincing results. From the irregularity of the incidence of epilepsy in lesions of the brain, Dr. Collier considered that it was not the lesion itself which caused the epilepsy, and that it was due to some associated condition not necessarily present with every lesion. As regards traumatic epilepsy, he had never seen a case benefited by operation and considered that operative measures were allowable only when indicated by definite physical signs other than the epilepsy.

The speaker then referred to the treatment of epilepsy. His experiences had convinced him that the less one departed from the routine of a normal healthy life and the fewer restrictions one made, the better it was for the patient. In children the ordinary course of education, discipline, games, and pleasures should be continued. Occupation was good for every epileptic. As regards dietetic treatment—such as the exclusion of meat—he considered that it did not appear to have any effect upon the course of epilepsy; as a general rule, alcohol should be forbidden. With the single exception of suppuration within the temporal bone, he believed that local bodily troubles—dyspepsia, constipation, uterine disorders—were of no importance either as causal factors or as excitants of the attack. In children who showed degrees of infantilism, backwardness, cerebral diplegia, and also in those with a low basic metabolic index, thyroid extract was sometimes a valuable adjunct in the treatment; in other cases, however, it might be harmful. Dr. Collier strongly condemned the view that medicinal measures should not be used in epilepsy until all other hygienic-dietetic measures had failed, and followed Gowers in the conviction that "apart from general regimen for the maintenance of good health, the treatment of epilepsy was purely medicinal." He believed that the remedies in common use acted rather by influencing the metabolic dyscrasia than by lowering the excitability of the nervous system. The method of treatment favoured was the giving of the remedy in a single dose at night in nocturnal epilepsy, in the morning in diurnal epilepsy, and both night and morning when the attacks occurred both day and night; he preferred not more than 1½ gr. of luminal as the morning remedy, and not more than 25 gr. of bromide at night.

Discussion.

Dr. ALDREN TURNER (London) said he was uncertain that all types of "idiopathic" epilepsy resulted from a metabolic dyscrasia, although he agreed that those cases which followed the exanthemata or other infective disorders probably resulted from this cause. Concerning an endocrine disturbance as a causative factor he was sceptical; the whole subject required fuller investigation. He considered that there was evidence that in a small group of epilepsies the disease was anaphylactic in nature and submitted that the undoubted value of a purin-free diet occasionally in epilepsy might be explained on this hypothesis. Dr. Turner's conception of epilepsy was that of "a morbid state characterised by periodic reactions of a very striking kind, and in the majority of cases tending towards chronicity and the development of some degree of mental enfeeblement." Research tended to limit the number of cases of idiopathic epilepsy and to place them in either the organic, the toxi-infective, the psychogenic, or the temperamental group. He believed that there was no doubt that some cases were purely psychogenic in origin.

Dr. TYLOR FOX (Lingfield) dealt with the use of luminal in epilepsy. He very rarely gave more than 2 gr. a day, as with larger doses—and sometimes even with 2 gr.—he had seen scarlatiniform rashes, symptoms of depression, and a dazed condition develop. He considered that with prolonged use luminal undoubtedly lost some of its effect; it was during the first two or three months of giving the drug that the most favourable results were obtained. The dosage, therefore, should be kept small and it should not be stopped suddenly or a marked increase in the frequency of fits would result. Emotional factors were of great importance in the determination of the attack; if the patient's environment was distasteful the fits were numerous, whereas when things were going well the fits were few. Environment was also of importance owing to the inability of the epileptic to adapt himself to the changing conditions of every-day life under which he was regarded as abnormal. Herein lay the case for colony treatment; in a colony the epileptic saw himself as a normal member of the community in which he lived. At Lingfield Colony over 20 per cent. of children lost their fits.

Dr. A. MCDOUGALL (David Lewis Colony) said that as in the majority of cases the epilepsy would persist throughout life, the physician should aim at preventing the patient from acquiring the unpleasant characteristics usually found in chronic epileptics. Every child developing epilepsy should be removed at once to a residential epileptic school. Witnessing attacks in other patients did not render an epileptic any more likely to have an attack himself; on the contrary, familiarity with the sight of fits often encouraged the patient to consider himself less afflicted than his neighbours.

Dr. STANFORD READ said that in his opinion the conception of epilepsy had been too narrow, because it had been regarded as a disease-entity instead of an end-result of some morbid process; because the convulsion itself had been the main source of interest with consequent neglect of the study of the individual in the inter-paroxysmal period; and lastly, because the psychic factor had not been adequately taken into account. Idiopathic epilepsy was just as much symptomatic as any other form, only the pathological basis was unknown. It was helpful to regard the nervous system as a mass of inter-related reflexes with any number of incoming stimuli and correspondingly manifold outward activities. Then we could see that a healthy organism was able through its nervous system so to distribute the energy received as to bring about a series of harmoniously adjusted activities. If, too, we viewed our nervous system as having evolutionary levels—physico-chemical, physiological, psychological—we might surmise that at any of them there might be, through disease, some block in energy distribution and discharge with resulting pent-up tension, which finally found its outlet in a convulsive attack. Many psycho-pathologists saw evidence at the psychological level of a blocking, pent-up tension, and sudden energic discharge in certain types of epilepsy. The study of the fit itself could not with any certainty differentiate for us the fit due to organic disease from one due to psychogenic causes. An investigation of the epileptic revealed in the majority of cases a lack of psychic balance which could not be regarded as secondary and something apart from the disease itself. Pierce Clark's painstaking work had taught us much on this point. The epochs of special physiological stress which not infrequently were productive of epilepsy were also commonly periods of psychic stress. Those untrained in psychological medicine did not elicit this latter factor and therefore denied its existence, or if noted they did not assess it correctly. Sadger and Stekel had published analytic investigations, and the latter stated he had had excellent therapeutic results. Dr. Stanford Read described a case of "grand mal" in which the history led one to suppose that psychogenic causes existed and where psychotherapy had certainly brought great benefit. A plea was made for a more detailed psychological study of those cases of epilepsy in which patent organic causes could not be demonstrated.

Dr. D. H. HARDCASTLE (London) considered that the essential reaction in epilepsy was a break in consciousness, which constituted a regression to a pre-conscious psychological level. He postulated a corollary between the epileptic fit and the "mass-reaction" dependent upon insufficient integration between the higher psychological and the lower physiological levels. Treatment, he considered, should be directed towards endeavouring to educate the child to adapt himself to his surroundings and to increase imperception.

The PRESIDENT expressed his belief that the ultimate cause of epilepsy might eventually be found to concern the sympathetic nervous system. He described a case of epilepsy associated with vagotonia which had apparently been cured by atropine. The vegetative nervous system, he considered, might over-react on either the sympathetic or the parasympathetic side.

Dr. W. A. POTTS (Birmingham) advocated the application of psychological treatment in epilepsy as early as possible. He had seen several cases, in which an important psychological basis existed, fail to improve with psychotherapy, either because a long period had elapsed since the disorder first appeared, or because the patient was unwilling to persevere with the treatment.

Dr. CARLILL raised the question of marriage in epileptics and drew attention to the precautions that should be taken by epileptics with regard to the risk of accidents. He also pleaded for greater accuracy in the diagnosis of epilepsy.

Dr. WORSTER-DROUGHT agreed with the opener that in many cass of epilepsy the probable basis was some form of metabolic disorder. Other facts not previously mentioned that supported this view were the frequent presence of a positive Widal, the hæmoclasic reaction for hepatic insufficiency and the "dysregulatio ammoniaci" of Danish observers. In the theory that epilepsy was due to food-protein idiosyncrasy and the reaction an anaphylactic state, Dr. Worster-Drought had very little belief. A series of cutaneous reactions with extracts of common foods, carried out on 40 cases of epilepsy, had not yielded a single positive result. He expressed surprise at Dr. Collier's experience of never having seen a case of traumatic epilepsy benefit by operation, as he (Dr. Worster-Drought) had met with several not only benefited but apparently cured by operation. He described two cases of non-penetrating injury in which operation had led to a complete cessation of the attacks. Regarding the treatment of epilepsy, his most favourable results had been obtained with combinations of luminal and sodium bromide. To illustrate this, he gave an analysis of 80 cases treated by different methods—simple bromide, borax and bromide, luminal, luminal and sodium bromide, intravenous injections of colloidal palladium, and dialacetin. He also agreed with other speakers that small doses of luminal were preferable—not more than 4½ gr. per diem.

Dr. J. W. SCHARFF (Singapore) considered that colony treatment tended to place a stigma upon the patient and believed that a better end-result could be achieved at home.

Dr. D. E. CORE (Manchester) raised the question of the frequency of death occurring in nocturnal epilepsy from the patient turning over and being suffocated by the pillow.

Dr. COLLIER then replied briefly to the various points raised.

FRIDAY, JULY 25TH.

The proceedings on the third day opened with a demonstration, by Dr. F. C. EVE (Hull), of the

Measurement of Kernig's Sign by Means of a Wheel Goniometer.

The defect in the ordinary method of eliciting Kernig's sign was that so much depended upon the amount of force used by the operator; hence it was often equivocal and could not be measured. When, however, the patient's leg was raised from the bed with the physician's hand placed just below the middle of the tibia, a time came when the knee flexed spontaneously. The angle which the leg then made with the horizontal was measurable by means of the wheel goniometer, an apparatus consisting of a spindle carrying a small graduated wheel which was weighted so that the 90° mark always floated uppermost.

Dr. A. FEILING (London) then opened a discussion on the

Differential Diagnosis and Treatment of Compression Paraplegia.

In order to keep the discussion within reasonable limits, Dr. Feiling excluded from consideration all cases of sudden or acute lesions of the spinal cord caused by trauma or acute myelitis of any kind. After a consideration of the physiological disturbances and pathological changes that followed compression of the spinal cord, he classified the causes of this form of paraplegia under two main headings: (1) extrathecal lesions, and (2) intrathecal lesions. Among the extrathecal lesions were the various diseases of the vertebræ, including caries, tumours, and spondylitis, and such conditions as aortic aneurysm, parasitic cysts, and tumours arising in the perithecal tissues. The intrathecal lesions included extramedullary and intramedullary tumours and the different forms of chronic meningitis. The general signs and symptoms were considered under two headings: first, those due to the direct effect of the lesion on the spinal cord and nerve-roots at some particular level (local symptoms); and secondly, those due to the interruption of the functions of the long tracts running in the cord (remote symptoms). The local symptoms included pain—localised to the area of supply of the nerve-roots involved—hyperæsthesia, and later, anæsthesia, while the remote symptoms were: (1) Motor—some degree of loss of voluntary power with spasticity and alterations in the reflexes; (2) sensory disturbances—developing later than the motor symptoms and appearing first in the feet and legs; and (3) affections of the autonomic system, especially in relation to the bladder and rectum, vasomotor changes, trophic lesions, and abnormalities of sweat secretion. Dr. Feiling then proceeded to describe the particular features of two of the most important and commonest forms of compression paraplegia—Pott's disease (about 5 per cent. of which cases showed spinal cord symptoms) and the paraplegia due to spinal tumours arising within the dural envelope. In spinal caries the cord might be injured in one of several ways—e.g., by pressure from an abscess, by tuberculous granulation tissue interfering with the circulation in the cord, by chronic pachymeningitis, and finally, very rarely by direct pressure from a displaced fragment of bone. The commonest form of spinal cord tumour was the intrathecal and extramedullary tumour, which arose inside the dural envelope often in connexion with a nerve-root, and exerted pressure on the cord over a particular segment or segments. This was a lesion which was essentially amenable to cure by surgery, provided the diagnosis had been made sufficiently early. The clinical picture of these extramedullary tumours was that of a slowly progressive paraplegia with clearly defined sensory loss, often preceded or accompanied by root symptoms and not infrequently with a tendency to the development of the Brown-Séquard syndrome. Certain diseases might simulate a compression paraplegia very closely; these were spinal syphilis, disseminated sclerosis, and syringomyelia. Examination of the blood and cerebro-spinal fluid would assist in excluding syphilitic meningomyelitis, but it may be mentioned that a positive Wassermann reaction in the blood does not negative a spinal tumour, and a positive reaction in the cerebrospinal fluid had been found in some cases of spinal cord tumour.

An X ray examination of the spine was essential, he said, in all cases in which compression paraplegia was suspected, and the cerebro-spinal fluid must also be investigated. The changes occurring in the cerebrospinal fluid in compression of the spinal cord often afforded conclusive evidence of a block in the free circulation of the fluid in the subarachnoid space. The fluid withdrawn by lumbar puncture might show excess of albumin without any excess of cells (" dissociation albuminocytologique ") or a Froin syndrome—viz.. the cerebro-spinal fluid coloured yellow (xanthochromia) and coagulating spontaneously on standing. The injection of lipiodol (a vegetable oil containing 40 per cent. of iodine and opaque to X rays) into the subarachnoid space at the cisterna magna with subsequent radiographic examination—a method recently introduced by Sicard—was a useful method of determining the site of the lesion. The lipiodol was heavy and tended to sink towards the bottom of the theca; if a block were present the substance was arrested at the upper limit of the obstruction.

Discussion.

Dr. **Carlill**, supplementing the opening paper with remarks from his own experience, pointed out that the site of a compressing lesion at certain levels could be determined by the attitude of the patient, and showed a photograph of a man with the attitude characteristic of a lesion just below the sixth cervical segment. He gave illustrations of the occurrence of priapism, with lesions not only in the cervical cord but in the dorsal and lumbar regions, and showed a photograph of a very large bedsore which had healed. Dr. Carlill next described a case in which cerebro-spinal fever led to compression paraplegia; meningitis circumscripta serosa was diagnosed and the diagnosis was supported by the failure of fluid to flow on lumbar puncture. This was confirmed by lipiodol, which showed complete obstruction in the subarachnoid channel, and proved by laminectomy. He also pointed out that to use lipiodol above a lesion it was not necessary to puncture the cisterna; the injection could be made into the cervical or dorsal theca provided the lesion was not high in the cervical region. Two other cases were quoted in which he had failed to obtain fluid by lumbar puncture, one of pineal cyst and the other following tetanus. He concluded by giving reasons for his belief that thecal puncture for diagnosis was an operation for the expert alone. The information it afforded at the time and in the laboratory made it the most important single operation in medicine.

Dr. J. **le F. Burrow** (Leeds) emphasised the occurrence of spinal rigidity in cases of spinal cord tumour and showed a case in which an extramedullary spinal tumour had been successfully removed. He considered the sensory examination of the utmost importance and advocated the use of Head's algesiometer for the purpose; small qualitative and quantitative changes in sensation were of great value in diagnosis. Cases of spinal caries in which paraplegia developed with great rapidity were instanced by Dr. Burrow, and he mentioned cases of paraplegia following slowly upon a slight trauma; knowledge of their pathology was slight. He agreed with the opener that a positive Wassermann reaction was occasionally found in the cerebro-spinal fluid from cases of spinal tumour—in highly albuminous fluids almost certainly non-specific. With regard to lipiodol, he was not in favour of its employment excepting in a few very difficult cases; he had seen retention of urine follow its use and the substance was difficult to handle.

Mr. G. **Jefferson** (Manchester) referred to the changes in the cerebro-spinal fluid and expressed his opinion that Froin's syndrome was very rare. Increased venous pressure (e.g., produced by compressing the jugular vein), he pointed out, normally caused a rise in the cerebro-spinal fluid pressure; if on lumbar puncture this normal rise was found to be delayed or absent (tested by means of a manometer), it afforded some evidence of a block being present in the intrathecal canal above the site of puncture. He drew attention to the fact that lipiodol was not so heavy as generally supposed, and that Sicard himself advocated waiting an hour after the injection before the X ray examination in order to admit of better gravitation. With reference to spinal caries, Mr. Jefferson said the incidence of paraplegia was about 5 per cent. of cases, although the actual condition is on the decline owing to the more efficient modern treatment of spinal tuberculosis. The chief argument against laminectomy was that 80 per cent. of cases recovered the use of the limbs with immobilisation treatment alone. If the paraplegia was stationary or increasing, laminectomy should be considered; operation was most likely to benefit when abscesses were present in the vertebral canal, and less likely when the paraplegia was due to pachymeningitis.

The **President** dealt with some of the surgical aspects of compression paraplegia and particularly with that form due to intrathecal tumour. He said that the most frequent position for such a tumour was between the anterior and posterior spinal nerve roots, being attached to one or the other. The effects of such a tumour were purely mechanical and typical in onset; as soon as the tumour became sufficiently large it would tend to compress the adjacent lateral column of the cord and eventually give rise to a Brown-Séquard type of syndrome. The first symptom was usually spontaneous " jumping " of the leg at night, followed in turn by occasional " giving way," dragging, and finally some degree of paralysis of the limb. The deep reflexes of the leg would then be increased, the plantar reflex extensor or indefinite, and the abdominal reflex of the same side reduced. Later would be found some loss of sensibility to heat and cold in the opposite leg extending upwards to within three or four segments of the actual level of the lesion. Such tumours were easily removed and the results of operation excellent. Concerning Pott's disease, if there was a flaccid paraplegia present that was not recovering, operation should be undertaken. In pachymeningitis root pains were usually present as well as muscular spinal rigidity. The most rapidly fatal cases of compression paraplegia were those due to sarcoma, while the most frequent secondary deposits involving the spinal cord were from growths arising in the kidney and suprarenal gland—more frequent than from the stomach.

Dr. **Worster-Drought** spoke of the difficulty in differential diagnosis in many cases of lesion in the lower cervical region of the spinal cord. especially between (1) syringomyelia with local undissociated anæsthesia and " central " pain and a compression of the cord by tumour; (2) syringomyelia with Brown-Séquard syndrome and intramedullary tumour; and (3) a pure spinal type of disseminated sclerosis and an early compression paraplegia without sensory changes. In the latter instance the colloidal gold reaction in the cerebro-spinal fluid might be of assistance; in his experience, however, the spinal type of disseminated sclerosis was more likely to give a " luetic " type of curve than a " paretic." He also referred to cases illustrating the difficulties and the differential diagnosis. With regard to Dr. Carlill's suggestion of puncturing the theca in the dorsal region instead of the cisterna magna, Dr. Worster-Drought pointed out that such an operation was not devoid of risk; in a certain percentage of normal individuals the posterior subarachnoid space is deficient in the dorsal region, the spinal cord being adherent to the dura-arachnoid. Consequently, there was an increased risk of inserting the needle directly into the cord. Froin's syndrome he had seen most frequently in connexion with cerebro-spinal fever, and in his experience was rare in other forms of compression paraplegia.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal health statistics of seven county boroughs for 1923:—

Name of county borough.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Leicester ..	239,700	19·2	11·6	1·1	1·3	1·9	38	84	3·5
Coventry ..	130,500	16·9	9·3	1·1	0·9	1·8	33	65	4·0
South Shields.	124,500	25·3	13·8	1·8	1·0	2·3	38	94	3·2
Walsall	100,400	23·3	11·7	1·1	1·0	2·0	45	94	1·7
Northampton.	93,230	17·8	11·6	1·1	1·5	2·2	31	57	4·2
Grimsby ..	85,620	22·9	10·5	1·2	1·4	1·9	34	79	4·1
W. Bromwich	77,600	24·2	12·5	0·8	0·9	3·3	36	88	2·7

Leicester.

Dr. C. Killick Millard says it is necessary to repeat again that shortage of housing accommodation is Leicester's most crying need. So far the housing committee have only been able to provide 766 new houses (up to March, 1924), while there are still 5600 applicants waiting. "So urgent and important," says Dr. Millard, "is this question of providing more working-class homes that it ought to take precedence over every other consideration." Another serious deficiency with much of the old cottage property in the central parts of Leicester is inadequate closet accommodation. For example, in Wyggeston ward out of 3117 houses inspected only 18·6 per cent. had their own W.C., while for 45·4 per cent. there were two houses to one W.C., and for 27·6 there were more than two houses to one W.C.; and in Newton ward out of 2024 houses inspected 20·4 had their own W.C., and for 45·5 per cent. there were two houses to one W.C., and for 34·2 there were more than two houses to 1 W.C. Dr. Millard considers the provision of extra W.C. accommodation for old property more important than any other improvement. Another defect in this class of property is the lack of adequate facility for washing clothes. Every new house has a washhouse outside or a copper in the scullery; but many of the old four-roomed cottages have neither. Dr. Millard points out that other towns provide municipal washhouses.

The question of the prevalence of goitre is discussed. Statistics based upon the medical inspection of school-children seem to suggest that there has been an increase in goitre since the early part of the century. There is no evidence, however, of any increase during the last four years. The percentage of girls in the secondary schools found to be suffering from enlargement of the thyroid during 1923 was 12·74 and the percentage of boys 2·75. A belief has been current in Leicester for several years that goitre has been more prevalent since the introduction of the Derwent water-supply, but inquiries made from other towns supplied from this source have not disclosed any increased prevalence of goitre, and the county medical officer of health for Derbyshire has pointed out that the Derwent watershed is not one of the districts of Derbyshire most affected by goitre. The prevention of goitre by small doses of potassium or sodium iodide is discussed, and it is pointed out that this method has been adopted in the schools of certain of the Swiss cantons for three years and that the extension of its use is recommended for all the schools in Switzerland.

Dr. Millard considers the evil effects of constipation, mentioning the belief by some that it is a predisposing cause of cancer. He suggests that instruction should be given to school-children in connexion with other health teaching with regard to this important matter. He thinks local education authorities might well act on the suggestion of the People's League of Health to have the lavatory accommodation of elementary schools thrown open to school-children before school hours. In view of the shortage of W.C. accommodation referred to above, this suggestion seems particularly applicable to parts of Leicester.

Coventry.

Dr. E. H. Snell records his conviction that the deterioration of housing conditions goes on faster than improvements. The necessity for the carrying out of repairs is greater than it was before the war and yet the staff of inspectors has been cut down by two. Dr. Snell points out, on the other hand, that a neighbouring city, recognising the growing urgency of this work, has actually increased its staff of inspectors to meet the position. Owing to the increasing importance of cancer as a cause of death, Dr. Snell publishes in full the leaflet drawn up by the Royal Society of Medicine on this subject. He also discusses the parts of the body affected, the age-periods in which deaths have occurred, and the proportional rates in those age-groups during the last 12 years. When a comparison is made between the age-groups 55 to 65 and 65 to 75 for the years 1913 and 1923 respectively, it appears that the deaths from cancer have shown a greater increase than the population living at each of these two age-groups, while for the age-group 45 to 55 there is a slight decrease. Under the heading water-supply, the desirability of covering in the tank at Spon End is pointed out. This tank is liable to pollution by dust from the neighbouring streets, and the examination of samples indicates that the water in the tank is less pure than on its entrance from the wells. Dr. Snell points out the bad conditions existing in some of the houses let in lodgings, certain of them being used as common lodging-houses without the proper stringent supervision being applied. Before the war a special subcommittee recommended the provision of a municipal common lodging-house. Dr. Snell is of opinion that a municipal common lodging-house would meet a great need, that it should not be of a pretentious character, and that there is no reason why it should not be self-supporting. The usual re-inspection of all houses converted from "back-to-back" to "through-ventilated" houses showed that without exception these houses are still properly occupied as through-ventilated houses.

The school report shows the accomplishment of more dental work. Only one-half, however, of the children found to require treatment received it, and Dr. Snell attributes this result to the apathy of the parents and does not think the nominal fee of 1s. per child is in any way responsible. Dr. Harrison Butler, the school oculist, reports in an interesting manner on errors of refraction. He regards myopia as a hereditary disease and thinks close work as a factor in the causation of myopia has been exaggerated. Myopia, he says, is very liable to show a decided advance after a debilitating illness. The following up of children during the last 12 years shows that the refraction of a child's eye alters in an extraordinary manner. Dr. Butler thinks that the proposal to exclude children with more than a specified amount of myopia from holding scholarships would be a great mistake, and that the suitability of a child to hold a scholarship should be left to the judgment of the ophthalmic surgeon of the clinic, who would take into account the history of the child and his family history. The roof open-air classes at Centaur Road schools were continued with great success and kept open for the first three months of the winter in response to a memorial signed by ratepayers. Miss E. K. Brown, the organiser of physical training, gives a valuable report on her work. One reads with interest that the land-drill for the breast-stroke in January and February enabled children to learn swimming more readily when the swimming season opened on April 16th.

South Shields.

Dr. William Nicoll states that the work embodied in the report was chiefly done under the supervision of his predecessor, Dr. Lyons. Numerous other alterations of staff took place during the year, the school medical service being most inconvenienced thereby. Dr. Nicoll says the high death-rate from tuberculosis is probably largely connected with the undesirable housing conditions which continue to prevail. Under the Housing Act of 1919 the council was authorised to build 1000 houses, but this number was subsequently reduced to 600. These 600 were completed during 1923 and comprise 305 houses of four rooms, 225 houses of five rooms, and 70 of six rooms. Dr. Nicoll is of opinion that there is a much greater demand for houses of two and three rooms to accommodate small families. Under existing conditions it is very difficult to get necessary repairs done. Overcrowding continues to get worse. As a direct consequence ash receptacles cannot contain the week's accumulation, and very many privies are quite unusable on several days of the week. During the year the council received permission to proceed with the erection of 290 houses under the Housing Act of 1923, and 130 of these were in course of erection at the end of the year. Lump sum grants of £100 per house to private builders under the 1923 Act have been also approved for 400 houses. Some figures are given from the Census for 1921. The density of population in South Shields is 48·6 persons per acre, the next highest borough in the county being Sunderland with 47·4. South Shields also contains the most densely overcrowded ward in the county—namely, Laygate, with a density of 206·8 persons per acre. South Shields again comes out worst in the county when judged by the Registrar-General's standard of the number of rooms per person available. The figure for South Shields is 0·71 room per person, Gateshead being a close second with 0·72, and the average for the whole county being 0·77. The proportion of the population overcrowded, in the sense of living more than two to a room, was shown to be 36 per cent. in the case of South Shields. The scheme for the conversion of the privies into w.c.'s has now begun in earnest and 1098 conversions were effected during the year.

Walsall.

Dr. James A. M. Clark states that the position as regards overcrowding has been but little relieved during the year, only 39 new municipal houses having been erected and 49 new houses by private enterprise. Only the bad cases of overcrowding could be dealt with, principally cases where single adult persons of opposite sexes were occupying the same bedrooms. A scheme for providing proper flushing cisterns for hand-flushed w.c.'s was in progress and was interrupted by the war. This scheme has gone slowly forward since the war, but in December last the health committee adopted the retrograde step of suspending this sanitary improvement. The combined Health and Baby Week in October was signalised by the opening of an extension of the open-air day-school, thus increasing its accommodation to 60. Dr. Clark reports a marked decline in rat infestation, many rat-infested buildings having been re-drained and others rendered rat-proof. The percentage of adulterated milk samples was very high, no less than 21 out of 99 samples being returned as adulterated. The penalties were not such as to act as deterrents; one case was fined 10s. and 10s. 6*d*. costs, 14 incurred costs of £1 each, five received cautions, and in one case the explanation was accepted. In his school report Dr. Clark states that the hygienic conditions of some of the older schools, both voluntary and council, are unsatisfactory, both lighting and ventilation being defective. He suggests that cheap improvement could be made by enlarging the window space.

Northampton.

Dr. J. Doig McCrindle gives some figures for Northampton from the Census. 19,893 structurally separate dwellings were occupied by 21,979 families. The size of the family was 4·45 persons in 1911 and 4·01 in 1921. The number of rooms per person was 1·27. The population living more than two to a room was 2393 in 1921 and 962 in 1911. Dr. McCrindle states that the drainage of many of the older buildings is defective and that the sewers in many districts are not self-cleansing and give rise to complaints with regard to sewer gas. In June the town council were asked by a resolution of a public meeting to adopt a model by-law for the compulsory use of "humane" methods of slaughtering. The butchers protested that there was no avoidable cruelty in the present methods, that the new instruments were not more efficacious, were not without danger, and that their use affected the quality of the meat. A deputation from the N.S.P.C.A. put forward statements controverting those of the butchers. Each side was asked to demonstrate its methods in actual practice. The demonstration took place early in 1924, and as a result the council decided to take no action for the present. Dr. McCrindle is of opinion that the provision and exclusive use of a public abattoir would be more effective in ensuring humane methods than any by-law. In November there was a small outbreak of anthrax cases in connexion with a tannery which handled skins from China. Some of the attacks were severe, but none were fatal. Dr. McCrindle discusses the prevalence of tuberculosis in the boot and shoe trade, and hopes to have more exact data when the later volumes of the Census are forthcoming. He shows that nearly half the mortality from tuberculosis of those engaged in occupations other than housework occurs among boot and shoe operatives.

Grimsby.

Dr. B. C. Stevens mentions that the system of purifying the water by chlorination has been adopted in the public swimming bath. A circular letter has been sent to the bakers and confectioners recommending that liquid whole egg should not be used for the making of sponge fingers, sponge biscuit, and small sponge cakes. Dr. Stevens refers to the great difficulty in educating or compelling rural milkers to be reasonably clean or to keep their cows reasonably clean.

West Bromwich.

Dr. R. Woolsey Stocks reports that Dr. Dorothy Unsworth has been appointed whole-time maternity and child welfare medical officer in lieu of the employment of four part-time general practitioners for this work. The change has resulted in an increased attendance. Dr. Stocks regrets the reduction of the staff of health visitors. Throughout the year there were only three health visitors at work, although, according to the latest standard of the Ministry of Health, the employment of six health visitors would be justified. In this connexion Dr. Stocks gives reason to think that although infant mortality is being reduced, there has been some increase in the mortality during the 1–5 age-period. Housing conditions remain very bad, and a large amount of the property is of such a poor character that no expenditure can make it satisfactory. In the report of the sanitary inspector we read that hitherto little action has been taken in West Bromwich as regards smoke abatement.

that such an operation was not devoid of risk; in a certain percentage of normal individuals the posterior subarachnoid space is deficient in the dorsal region, the spinal cord being adherent to the dura-arachnoid. Consequently, there was an increased risk of inserting the needle directly into the cord. Froin's syndrome he had seen most frequently in connexion with cerebro-spinal fever, and in his experience was rare in other forms of compression paraplegia.

Special Articles.

THE ANNUAL REPORT OF THE CHIEF MEDICAL OFFICER OF THE MINISTRY OF HEALTH.[1]

THE annual report of the Chief Medical Officer to the Ministry of Health shows the Department to have been fully and usefully occupied. The returns published by the Registrar-General relating to births, deaths, and infectious disease, as well as the various data in respect of invalidity under the National Insurance Acts, have been relied upon for the statistical information, while this is supplemented by the investigations undertaken by the medical officers of the Department and of other bureaus interested in the physical, industrial, and social welfare of the people, as well as by reports of medical officers of health, both annual and special.

Sir George Newman has arranged the vast mass of information thus indicated in 12 chapters, the first three of which give an account of the present state of public health in England, of the general epidemiology of the country, and of the relations of public health to infectious diseases of exotic origin. Special sections then deal with tuberculosis, venereal diseases, and maternity and child welfare, the section which has tuberculosis as its subject being a very full statement of the existing machinery both for prevention and cure. Informing summaries of the work of the insurance medical service and of the Poor-law medical service follow, while a valuable section treats of the relation of food to health and disease. An account of local and port sanitation and of international health work bring us to the general conclusion which follows :—

THE RECORD OF 1923.

If we endeavour, writes Sir George Newman, to take a bird's-eye view of the material facts of the physical life and health of the English people during 1923, we shall base our deductions upon four main groups of data :—

(i) The number of births registered in 1923 was 758,131, which showed a decline of 22,000 on 1922 (as compared with a fall of 70,000 in the previous year), and which yielded a birth-rate of 19·7 per 1000.

(ii) The number of deaths in 1923 was 444,786, less by 42,000 than in the previous year. The total death-rate (11·6 per 1000 persons) was the lowest ever recorded in this country; but 40 per cent. of these deaths occurred under 50 years of age.

(iii) The infant mortality-rate—the death-rate of infants under 1 year of age per 1000 born—was also the lowest registered—namely, 69. This means the country saved not less than 45,000 babies' lives over and above the average saving obtained in 1901–10. This is perhaps the greatest recent triumph of preventive medicine.

(iv) The number of cases of epidemic and infectious disease notified in 1923 was 314,183, as compared with 422,919 in the previous year.

These facts and figures give us a record year, but we must be circumspect in drawing unduly favourable conclusions. In the first place, it is obvious that the general death-rate in this country cannot be diminished indefinitely. A time must come when no further improvement in the death-rate is possible, since all who live must die, and even if nobody died under four score and ten years, there would still be a death-rate. It is the number of unreasonably premature deaths which we must seek to reduce. We cannot possibly say when the most favourable death-rate has been reached, nor even what that death-rate should be, but very simple arithmetical considerations will show us that there is a limit; and whilst it is not suggested that there is a "law" of decrement of mortality, it is certainly true that some process of diminishing returns does operate, and that it is incorrect and fallacious to measure the public health conditions of a country wholly by changes in the general death-rate. In the second place we must bear in mind that the particular low mortality in 1923 is in part an expression of the present phase of distribution of our population in regard to age, and to propitious meteorological conditions conducive to the health of infants and elderly persons. Then again, we must to some extent attribute to good fortune the fact that we were spared widespread epidemics. Nevertheless, after all the necessary qualifications have been made, the health of this country in 1923 was very encouraging, and certainly the public expenditure on its maintenance is at present yielding a very high rate of interest in life and well-being.

On the other hand, there is much sickness and physical impairment, which is directly resulting in absence from work, broken time and restricted productivity. Probably such loss of time due to sickness, most of which is preventable, costs the country not less than ten times more than that which it loses owing to strikes and labour disputes. It must not be forgotten that we are in friendly competition with communities which are giving more public attention to social and health problems than we are ourselves. *National ill-health loses time and reduces production* as well as resulting in suffering, discontent, and premature death, and this aspect of the question must be borne in mind. Unfortunately, also, we are still the victims, in some cases the willing victims, of small-pox and venereal disease. Influenza and encephalitis lethargica, bronchitis and pneumonia, tuberculosis and cancer still demand a heavy toll. Many valuable lives are thus being sacrificed, and far too many of our deaths occur under 50 years of age. It is the business of the Public Health Service to concern itself in all that saves life, that postpones the event of death, that reduces sickness and invalidity, and that increases human energy, enlarges its capacity and develops productivity. Thus it should contribute to the efficiency and happiness of life. It is this wider view of their responsibilities that I commend to the local authorities charged with the duty of the sound administration and practice of preventive medicine. It is theirs by wise expenditure and economical organisation to aid and facilitate the rearing and maintenance of a healthy race of people and to continue to attack infection and all forms of insanitation, sickness, and invalidity. The public health is the primary asset of the nation's welfare, whether measured by employability and production, or by length of days, or by personal well-being.

The exceptional features of the year's work are referred to under the respective headings. Generally speaking, it may be said that the experience of the year confirms the broad health policy with which the Ministry of Health was initiated and which in large part it inherited from its predecessors. That policy was fully stated in my first annual report in 1920 and in a special report published the year before. We have steadily pursued these aims. If we are wise we shall continue to follow them, regardless of all temptations to neglect, to idleness, to misdirection, and to the chase of will o' the wisps or "wandering fires." The health organisation of a nation is statecraft. It cannot be established by chance or caprice. It must be broad based on sound foundations. The immediate future seems to require of us that we should have particular regard to the following :—

(*a*) the need for the education of the people in hygiene;

(*b*) wide and comprehensive concentration on the strongholds of disease;

(*c*) the careful coördination and direction of means to ends; and

(*d*) systematic research and investigation.

Public Education in Hygiene.

For a number of years past, in reports to the Board of Education and elsewhere, I have sought to draw attention to the need for public education in hygiene. Last year in my report to your predecessor the following words occur :—

"Preventive medicine is an aspect of social evolution, which involves wide and deep apprehension and practice in society as a whole. It concerns individual habit and communal custom. It must not only follow in the wake of growing knowledge and await that knowledge, but it is dependent on the readiness of the great mass of the people to accept, understand and apply that knowledge, at least in substance and principle. All wise government no doubt depends on the assent of the governed, but in public and private medicine an even fuller assent is needful, if the individual is to reap his full advantage and at the same time act loyally as a member of the community. In fact, he is under obligation to cultivate his own health and capacity, and so to conduct himself as not to conduce to the hurt or risk of his neighbours. Hence the progress of preventive medicine depends in extraordinary degree upon the enlightenment and education of the people. There is no doubt that owing to the national system of education, to voluntary educational movements and societies, and to the valuable agency of the press and public opinion, such enlightenment is proceeding apace. Yet it has far to go."

In view of the importance of the subject, you have called for a special memorandum which will be published at an early date, and it is therefore unnecessary further to deal with the question here. It is significant that the official reports of medical officers of health for 1923 show increased

MENTAL HOSPITALS SERVICE.

THE annual report for 1923 of the *Royal Eastern Counties Institution for the Mentally Defective, Colchester,* reveals a satisfactory financial position, despite the expense involved in recent extensions. When it is remembered that this institution possessed only 400 beds in 1914, and now has 1070, and that a proportion of the annual cost of upkeep has to be met by voluntary contributions, the progress made during this period of ten years appears truly remarkable. Perhaps nowhere else are there more complete facilities for the education of all grades of defectives; the inmates are divided into no less than 25 classes, and every effort is made to render the members of each as useful to society as careful training can make them. Unfortunately, recent admissions have included an increasingly high proportion of low-grade patients. Boards of guardians are sending the better grade and well-behaved cases to smaller homes and workhouses, where their capabilities for work without previous elaborate training are naturally appreciated. The Mental Deficiency Act is intended to apply equally to this class of case, a fact not apparently appreciated by local authorities. It was not intended, and it is not just, that such institutions as this should be filled largely with low-grade cases requiring much nursing care, while cases capable of deriving greater benefit from training are kept elsewhere. One effect of this development, which interferes seriously with the valuable work of this institution, is that "the low-grade classes get full, and though there may be plenty of beds in other classes, cases have to be refused." As the medical superintendent, Dr. F. D. Turner, remarks, the Mental Deficiency Act has never yet been fully applied; there is nothing like enough accommodation, and at the present time numerous adult defectives are in asylums. Sooner or later the accommodation on one side or the other will be extended, and it will then have to be decided whether such patients are to be sent where they really belong, and existing asylum beds employed for cases of acquired and recoverable insanity. The functions of these two classes of institution are totally distinct; one exists for training and the other for therapy, and when the question is viewed from this standpoint there can be no two views as to the proper place for the adult defective. Further accommodation under the Act is much required, and the transfer of such patients as these from the asylums will leave the latter with a number of beds which in many cases are badly needed for the insane. Progress is being made at this institution with the "hostel" and "parole" treatment, although the difficulty of obtaining outside employment for these cases is still considerable. Bridge Home, the new building, owes much of its domestic equipment and stores to the industry of inmates in the existing workshops. A kinema is being installed, and a film showing the work of the institution is being exhibited in England and even abroad. Both in detail and in its observations on general questions in mental deficiency this report is of outstanding interest.

The report of *The Retreat, York,* for 1923 is a very readable survey of the events of the year in that mental hospital, including observations on two or three subjects of general interest. Several structural changes are being made, the most important of which is the building of a new nurses' home. Throxenby Hall, Scarborough, used in the past as a holiday and convalescent home, has been given up, and this year a country house elsewhere was rented in its place. Millfield, another country house not far from the Retreat itself, which was acquired four years ago as a home for incipient and "borderland" cases, is henceforth only to be used for quiet chronic insane. It was with great regret that the original purpose for which this building was intended had to be given up. Two reasons decided this step—the heavy financial loss entailed, and the impossibility for the Retreat medical staff of devoting sufficient time to the psychotherapeutic treatment necessary for such patients. Dr. Henry Yellowlees, the medical superintendent, points out that with six real "borderland" cases, each requiring a minimum of four private interviews per week, "24 hours of somewhat exhausting and highly specialised work" would be entailed. All the cases treated there during the past have not required such intensive treatment, and a large number have benefited. That this step has by no means closed the avenue to institutional care for such patients may be gathered from the fact that no less than 48 per cent. of admissions to the Retreat itself were voluntary boarders. The policy of encouraging voluntary admissions has on the whole worked well, only very few of these patients requiring eventual certification. One voluntary boarder who appeared to have recovered fully, and was indeed making arrangements for departure, committed suicide by hanging. As Dr. Yellowlees observes, this case illustrates a problem of the greatest difficulty: "The acutely suicidal patient is, in comparison, an easy proposition. . . . A time comes when a patient is convalescent, and precautions *must* be relaxed. He will not recover if he is not trusted, and obviously we cannot prove that he is not suicidal as long as he has no possible opportunity of making an attempt." The malarial treatment for general paralysis, and the search for and treatment of focal infections, have been applied in a small number of suitable cases. It is also recorded that one of the padded rooms has been converted into a linen cupboard, a fact of small importance in itself, but deriving a certain interest from the context. "Only one padded room now exists at the Retreat. It has been largely used during the year by a gentleman who regards permission to sleep therein a great privilege, awarded for good behaviour."

The annual report for 1923 of the *Down District Lunatic Asylum, Downpatrick,* contains the same excellent series of 13 photographs of the buildings as appeared in last year's issue; the impression created is one of prosperity and efficiency, which stands in sharp contrast with the condition of many asylums in other parts of Ireland. There is accommodation for 800 patients, and the number now resident is only 716. Particular attention is being devoted to the training of nurses. The "representatives of the staffs" are said to have demanded the withdrawal from the service of those who fail to pass such a test (as an examination) after reasonable opportunity. Thirty-one nurses and attendants have passed in various parts of the examination for the certificate of the Medico-Psychological Association. The recovery-rate for this hospital during the year under review was over 50 per cent.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 9TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely—Small-pox, 37; scarlet fever, 1260; diphtheria, 576; enteric fever, 99; pneumonia, 378; puerperal fever, 42; cerebro-spinal fever, 3; acute poliomyelitis, 30; acute polio-encephalitis, 2; encephalitis lethargica, 48; trench fever, 1; dysentery, 4; ophthalmia neonatorum, 118.

Deaths.—In the aggregate of great towns (including London) there were 2 deaths from enteric fever, none from small-pox, 7 from scarlet fever, 24 from diphtheria, 18 from measles, and 18 from influenza. In London itself the diphtheria deaths numbered 6.

INDEX TO "THE LANCET," VOL. I., 1924.

THE Index and Title-page to Vol. I., 1924, which was completed with the issue of June 28th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers wishing to receive the Indexes regularly as published should indicate this desire.

Special Articles.

THE ANNUAL REPORT OF THE CHIEF MEDICAL OFFICER OF THE MINISTRY OF HEALTH.[1]

THE annual report of the Chief Medical Officer to the Ministry of Health shows the Department to have been fully and usefully occupied. The returns published by the Registrar-General relating to births, deaths, and infectious disease, as well as the various data in respect of invalidity under the National Insurance Acts, have been relied upon for the statistical information, while this is supplemented by the investigations undertaken by the medical officers of the Department and of other bureaus interested in the physical, industrial, and social welfare of the people, as well as by reports of medical officers of health, both annual and special.

Sir George Newman has arranged the vast mass of information thus indicated in 12 chapters, the first three of which give an account of the present state of public health in England, of the general epidemiology of the country, and of the relations of public health to infectious diseases of exotic origin. Special sections then deal with tuberculosis, venereal diseases, and maternity and child welfare, the section which has tuberculosis as its subject being a very full statement of the existing machinery both for prevention and cure. Informing summaries of the work of the insurance medical service and of the Poor-law medical service follow, while a valuable section treats of the relation of food to health and disease. An account of local and port sanitation and of international health work bring us to the general conclusion which follows:—

THE RECORD OF 1923.

If we endeavour, writes Sir George Newman, to take a bird's-eye view of the material facts of the physical life and health of the English people during 1923, we shall base our deductions upon four main groups of data:—

(i) The number of births registered in 1923 was 758,131, which showed a decline of 22,000 on 1922 (as compared with a fall of 70,000 in the previous year), and which yielded a birth-rate of 19·7 per 1000.

(ii) The number of deaths in 1923 was 444,786, less by 42,000 than in the previous year. The total death-rate (11·6 per 1000 persons) was the lowest ever recorded in this country; but 40 per cent. of these deaths occurred under 50 years of age.

(iii) The infant mortality-rate—the death-rate of infants under 1 year of age per 1000 born—was also the lowest registered—namely, 69. This means the country saved not less than 45,000 babies' lives over and above the average saving obtained in 1901–10. This is perhaps the greatest recent triumph of preventive medicine.

(iv) The number of cases of epidemic and infectious disease notified in 1923 was 311,183, as compared with 422,949 in the previous year.

These facts and figures give us a record year, but we must be circumspect in drawing unduly favourable conclusions. In the first place, it is obvious that the general death-rate in this country cannot be diminished indefinitely. A time must come when no further improvement in the death-rate is possible, since all who live must die, and even if nobody died under four score and ten years, there would still be a death-rate. It is the number of unreasonably premature deaths which we must seek to reduce. We cannot possibly say when the most favourable death-rate has been reached, nor even what that death-rate should be, but very simple arithmetical considerations will show us that there is a limit; and whilst it is not suggested that there is a "law" of decrement of mortality, it is certainly true that some process of diminishing returns does operate, and that it is incorrect and fallacious to measure the public health conditions of a country wholly by changes in the general death-rate. In the second place we must bear in mind that the particular low mortality in 1923 is in part an expression of the present phase of distribution of our population in regard to age, and to propitious meteorological conditions conducive to the health of infants and elderly persons. Then again, we must to some extent attribute to good fortune the fact that we were spared widespread epidemics. Nevertheless, after all the necessary qualifications have been made, the health of this country in 1923 was very encouraging, and certainly the public expenditure on its maintenance is at present yielding a very high rate of interest in life and well-being.

On the other hand, there is much sickness and physical impairment, which is directly resulting in absence from work, broken time and restricted productivity. Probably such loss of time due to sickness, most of which is preventable, costs the country not less than ten times more than that which it loses owing to strikes and labour disputes. It must not be forgotten that we are in friendly competition with communities which are giving more public attention to social and health problems than we are ourselves. *National ill-health loses time and reduces production* as well as resulting in suffering, discontent, and premature death, and this aspect of the question must be borne in mind. Unfortunately, also, we are still the victims, in some cases the willing victims, of small-pox and venereal disease. Influenza and encephalitis lethargica, bronchitis and pneumonia, tuberculosis and cancer still demand a heavy toll. Many valuable lives are thus being sacrificed, and far too many of our deaths occur under 50 years of age. It is the business of the Public Health Service to concern itself in all that saves life, that postpones the event of death, that reduces sickness and invalidity, and that increases human energy, enlarges its capacity and develops productivity. Thus it should contribute to the efficiency and happiness of life. It is this wider view of their responsibilities that I commend to the local authorities charged with the duty of the sound administration and practice of preventive medicine. It is theirs by wise expenditure and economical organisation to aid and facilitate the rearing and maintenance of a healthy race of people and to continue to attack infection and all forms of insanitation, sickness, and invalidity. The public health is the primary asset of the nation's welfare, whether measured by employability and production, or by length of days, or by personal well-being.

The exceptional features of the year's work are referred to under the respective headings. Generally speaking, it may be said that the experience of the year confirms the broad health policy with which the Ministry of Health was initiated and which in large part it inherited from its predecessors. That policy was fully stated in my first annual report in 1920 and in a special report published the year before. We have steadily pursued these aims. If we are wise we shall continue to follow them, regardless of all temptations to neglect, to idleness, to misdirection, and to the chase of will o' the wisps or "wandering fires." The health organisation of a nation is statecraft. It cannot be established by chance or caprice. It must be broad based on sound foundations. The immediate future seems to require of us that we should have particular regard to the following:—

(*a*) the need for the education of the people in hygiene;
(*b*) wide and comprehensive concentration on the strongholds of disease;
(*c*) the careful coördination and direction of means to ends; and
(*d*) systematic research and investigation.

Public Education in Hygiene.

For a number of years past, in reports to the Board of Education and elsewhere, I have sought to draw attention to the need for public education in hygiene. Last year in my report to your predecessor the following words occur:—

"Preventive medicine is an aspect of social evolution, which involves wide and deep apprehension and practice in society as a whole. It concerns individual habit and communal custom. It must not only follow in the wake of growing knowledge and await that knowledge, but it is dependent on the readiness of the great mass of the people to accept, understand and apply that knowledge, at least in substance and principle. All wise government no doubt depends on the assent of the governed, but in public and private medicine an even fuller assent is needful, if the individual is to reap his full advantage and at the same time act loyally as a member of the community. In fact, he is under obligation to cultivate his own health and capacity, and so to conduct himself as not to conduce to the hurt or risk of his neighbours. Hence the progress of preventive medicine depends in extraordinary degree upon the enlightenment and education of the people. There is no doubt that owing to the national system of education, to voluntary educational movements and societies, and to the valuable agency of the press and public opinion, such enlightenment is proceeding apace. Yet it has far to go."

In view of the importance of the subject, you have called for a special memorandum which will be published at an early date, and it is therefore unnecessary further to deal with the question here. It is significant that the official reports of medical officers of health for 1923 show increased interest in this matter. Much admirable popular instruction is now undertaken in maternity, tuberculosis, and venereal disease. But it needs development, expansion, and even wider dissemination. It must begin in the elementary schools, but it should continue all through life. It should be particularly concerned with personal hygiene, nutrition, and the right use of milk and other foods. It should be definitely related to the whole sanitary service, and to the improvement of national physique and capacity. "To make the unfit fit," said the late Dr. Herman Biggs of New York, whose recent death we all deplore, "is a worthy task, but to make the fit fitter is a larger and higher achievement."

---

[1] H.M. Stationery Office and all Booksellers. 1924. Pp. 211. 5s. net.

Need for Comprehensive Practice.

The modern development of the Public Health Service has been characterised by an expansion and amplification of the former practice of sanitation and has found expression in more direct methods of attack on particular diseases. This has been due partly to the stabilised condition of the older sanitary measures and partly to the growth of knowledge of the causes of disease and the means of their prevention. So long as due and continuous attention be given to fundamental sanitation and the ordinary practice of hygiene these wider applications of preventive medicine are likely to prove wholly advantageous. But if they be used in substitution for a sanitary environment and healthy living, or even if they be used apart from a sanitary environment in its fullest sense, then we must not expect them to yield their full value. Take tuberculosis—the direct attack on this disease, the treatment of the affected person, the dispensary, the sanatorium, the hospital, adequate after-care—this is all as it should be, but it is not enough. The nutrition of the whole people, life in the sunlight and open air, proper housing, clean workshops, a wholesome milk-supply, healthy habits—these also are necessary, even more necessary, for they are the means of prevention, they reduce infection and they fortify the resistance of the individual. Take venereal disease—the special clinics where early and effective treatment is provided are of immediate importance, for they heal the patient and make him non-infective; but *avoidance of infection*, chastity, high moral standards and all that subserve their practice provide the true prevention. Take maternal mortality—as I have already pointed out, the only sound course is to prepare against it rather than attempt at the eleventh hour to save a desperate situation. The education of the medical student in obstetrics, improved midwifery, the abolition, or proper equipment, of the "handy woman," the stamping out of unjustifiable "covering" by the medical attendant, the provision of maternity homes or otherwise securing their facilities, the universal adoption by all expectant mothers of antenatal hygiene—these are the ways, and the only ways, of reducing maternal mortality in the long run. Even cancer is a disease to which we must apply broad principles. *Surgical aid at an early stage of the disease* is now the proper course—but I do not doubt that the time will come when all men will understand that a healthy way of life, the true physiology of the normal functioning of the body, combined with some degree of natural or acquired immunity, will be our best protection against this scourge. By all means let us seek to apply the direct means of amelioration in all diseases as they are made clear to us by investigation and experience; but all the time our building must be on sure and solid foundations—(1) the nutrition of the body of man, (2) the sanitary environment in which it survives, and (3) the biological laws of Nature.

The Direction of Means to Ends.

Another point which emerges continually in the text of this Report is the adaptation and coördination of means to ends. In 1919 the Ministry published a memorandum which set out in detail a health programme for every local authority and suggestions as to the way in which such a national standard could be fulfilled.[2] This document has had a wide circulation, but there are still many authorities, and I must add many medical officers of health, who have apparently paid no regard to it. They still "muddle on" from hand to mouth, the victims of every passing whim or popular "stunt," instead of organising their work as responsible and competent men charged with the duty of directing the public service of their district on behalf of all who have the fortune, or misfortune, to live within its boundaries. Yet public health workers should be inspired by science and by statecraft, for upon their labours depend the lives and fate of vast populations. The opportunity is theirs, and the instrument is in their hands. There is all the machinery of the sanitary service, there is the maternity and infant welfare service, the school medical service, the health insurance system, the Poor-law medical service, the sanitary cordon—they are all there, provided by statute, expressive of the will of the people; but in many districts they are not being sufficiently used or sensibly applied; workable machinery, but unused and inadequately working. It is not money they lack, but will-power and such careful, economical and foreseeing coördination and direction as the particular needs of each area indicate, the backward authorities striving to emulate the more advanced and enlightened. The progress of the science and art of medicine in the last quarter of a century has, it is true, outstripped the organisation of our sanitary, Poor-law, and education authorities. The new wine is being poured into old wine-skins. But what is much more pertinent to our labours, *we fail in hundreds of sanitary districts to use the facilities provided*. On the whole the existing facilities are reasonably well furnished; but all too often people fail to use them, and the authorities fail to coördinate them.

Research and Investigation.

The fourth great need of the immediate future is research. Everything could be done better than it is being done—if we only knew how to do it. We are still in the dark as to the cause of measles, of influenza, of encephalitis lethargica, of rheumatism, and of cancer. Happily, in 1923 there was a great awakening in the public mind in regard to the importance of research in cancer. It would be difficult to exaggerate that importance. All good citizens should learn to recognise it, for the truth here, when found, will inevitably lead to the conquest of new kingdoms of understanding of man's life. Definite and constructive progress is being made, and this should be our encouragement. Every insurance doctor and every medical officer all through the public services should be a man of research, of inquiry, of open and seeking mind, bent on investigation into the causes of things; and I must add that every insurance committee or local authority served by such men should be alive to the duty and opportunity of research, the true scientific method—providing for it, encouraging it, and applying its spirit in their own administration as well as to the growth of knowledge.

THE MAYO CLINIC, ROCHESTER, MINN., U.S.A.

(FROM A SPECIAL CORRESPONDENT.)

The Ketogenic Diet in Epilepsy.

AT a meeting of the Northwest Pediatric Association held here on August 2nd Dr. M. G. Peterman, of the Clinic, read a short paper on the Ketogenic Diet in the Treatment of Epilepsy. The instigation of this treatment was inspired by a consideration of the factors operating in starvation of epileptics, which would appear to be successful in some cases. One important effect of starvation is the production of ketosis, and it was felt that a less drastic method of producing ketonæmia might be equally effective in controlling the seizures. Certain theoretical considerations support this somewhat empirical procedure. Of the three ketone bodies diacetic acid alone has a toxic effect, and this effect is similar to that of the anæsthetics. In common with these, diacetic acid is soluble in fats and lipoids, and presumably shares their property of penetrating the lipoids of the central nervous system. The beneficial effect of chloroform or ether anæsthesia in suppressing epileptic attacks for a considerable length of time has been frequently noted, and it seems not impossible that diacetic acid might similarly be of value. Feeding or injecting diacetic acid is not practicable, as the body easily converts it into non-toxic substances. The ketonæmia is produced by a restriction of carbohydrate metabolism. Since protein may be largely converted into glucose, this is restricted to the minimal requirement of 1 g. per kilogramme of body-weight in children and about 0·75 g. in adults. About 10 to 15 g. of carbohydrates are given, and the balance of the total calories, which should not exceed the actual metabolic requirements, is made up from fats. Vitamin and salt requirements must not be considered in planning the diet. The diets should be instituted gradually, as they may not be tolerated at first. Of the 20 cases reported under this regimen, 17 have been entirely free from convulsions for periods varying from 1 to 15 months. Two of the cases were considerably improved, but still had occasional convulsions. One of them is a case of hysteria who has been subjected to severe mental traumata, and in the other case it is not known if the ketosis still exists. The parent of this last patient is under treatment for syphilis. The one entirely unsuccessful case is a post-encephalitic undergoing mental degeneration. The children do not seem to suffer in any way from the effects of ketosis. Two of them had gastro-intestinal upsets, and were put on general diets with restricted carbohydrate for a short time. Both remained free from attacks and on recovery returned to the ketogenic diet.

[2] Outline of the Practice of Preventive Medicine. Cmd. 363. 6*d*.

Pyelitis in Children.

Dr. H. F. Helmholz, President of the Association, and head of the Department of Pediatrics at the Mayo Clinic, has reported a series of eight cases of pyelitis in children resulting from a condition described as "cord bladder." The term "cord bladder" is intended to describe an atonic condition of the organ resulting from a congenital defect in its innervation. Spina bifida or spina bifida occulta is present in about half the cases, and dribbling, which is frequently present, is a very suggestive symptom. As much as 180 c.cm. of residual urine were removed from the bladder in one instance. The result of this atony, which characterises the entire urinary tract in these cases, is a damming back and stagnation of urine in consequence of which pyelitis easily develops. Cystograms were shown in which injected fluid had passed with ease up the dilated ureters into the pelvis of the kidney. Dr. Helmholz has so far been unable to devise any effective method of treatment.

Bust of Harvey Presented to the Mayo Foundation.

At the weekly meeting of the general staff on July 30th, Dr. L. G. Rowntree, of the Mayo Clinic, presented to the Foundation a bronze bust of Harvey, which he had greatly admired at the Physiological Congress held in Edinburgh last year. The bust was one of two executed for the Congress by Pilkington Jackson. After returning to this country Dr. Rowntree wrote to Mr. Jackson and succeeded in obtaining the identical bust which had stood behind the president of the Congress at its opening meeting. After an impressive and laudatory appreciation of Harvey's genius, Dr. Rowntree closed by saying: "It is my fondest wish, in fact my prayer, that with this bust of Harvey his spirit may descend upon us and permeate the entire work of the Foundation and of this institution as a whole, and may abide here always." Dr. Wilson, in a speech of acceptance on behalf of the Mayo Foundation, referred to the similarity, both physical and mental, between Harvey and Shakespeare, and thanked Dr. Rowntree for a gift which he characterised as particularly appropriate to a Foundation established for the encouragement of medical education and research.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Regius Professor of Surgery, Glasgow University.

Mr. Archibald Young, who has been appointed by the Crown authorities to the Regius Chair of Surgery in Glasgow University in succession to the late Sir William Macewen, assumes his duties with a wide experience of teaching, both clinical and systematic. For five years he was lecturer in surgery in the Western Medical School, until 1913, when he was elected professor of surgery in the Anderson College of Medicine, of which, for the past year, he has acted as Dean. Prof. Young is 50 years of age. In 1893 he took the B.Sc. degree with anatomy and physiology as principal subjects, and in 1895 he graduated M.B., C.M. with high commendation. In 1913 he became F.R.F.P.S. Glasg. after examination. After a period as private assistant to Prof. Joseph Coats in the department of pathology, Mr. Young became associated with Sir William Macewen as his senior assistant on the staff of the University. Thereafter he held the usual junior positions on the surgical staff of the Western Infirmary, and in 1917 he was appointed visiting surgeon to that institution. For the previous nine years he had acted as consulting and visiting surgeon to the Broadstone Jubilee Hospital, Port Glasgow.

Prof. Young has made many exact and well-balanced contributions to surgical literature. As a civil surgeon in the South African War he gave minute attention to the features of injuries of peripheral nerves, and his report on this subject was included as an appendix to the official Surgical Report of the War. During the European war his position as neurological expert to the Glasgow district gave him access to a mass of similar material, and his painstaking observations were presented at the last meeting of the Société Internationale de Chirurgie. He is well known as an exponent of the operative treatment of fractures, and his work on this subject has been widely quoted. Earlier in his career he elaborated a modification of the Wolfe-Krause method of whole skin grafting, and incorporated the results obtained by his method in a paper still recognised as authoritative. Prof. Young may be relied upon to stimulate surgical research in his department, and at the same time to maintain the high level of surgical training which characterised the Glasgow School of Surgery under his old chief, Sir William Macewen.

The New South-Eastern Counties Sanatorium.

Dr. Charles Cameron has just issued his first report on the East Fortune Sanatorium, covering the period from the opening on Dec. 1st, 1922, up to May 15th last. He is modest about the scope of such a report and refuses to draw inferences from the admissions in regard to the incidence of various types of disease; for, as he truly says, the admissions represent efforts at treatment, they give no indications of the numbers of varying ages who remain at home. The methods of treatment adopted have been strictly orthodox, and Dr. Cameron makes no secret of the fact that he has enforced strict hospital discipline at the sanatorium, with the result that a number of patients have refused to coöperate with him—15 adults left or were removed by their relatives. Fortunately, however, a large proportion of his patients are children with whom no such difficulty arises. Adventitious aids to treatment were unimportant. It was wisely decided to continue during the winter months by means of carbon-arc light the treatment by sunshine, the supply of which had already been scarce enough in the summer, and tuberculin in two forms was being used, but Dr. Cameron regards the part played by drugs as quite subsidiary, although cod-liver oil may prove beneficial, especially in cold and sunless weather. Of the 103 patients so far discharged, one child with abdominal tuberculosis died, three adults with pulmonary tuberculosis were worse, while the condition of the remainder was stationary or better, arrest of the disease being recorded in two adults (lungs) and 15 children (lungs 3, glands 8, spine 1, abdomen 2, bladder 1). The duration of residence being primarily determined by willingness to stay, Dr. Cameron's aim is to retain patients until the disease shows evidence of being healed.

The Henry Brock Vale of Leven Cottage Hospital.

A well-equipped cottage hospital has been established at Broomley House, Balloch, for the inhabitants of the Vale of Leven through the munificence of the late Mr. Henry Brock, of Darleith, who left a bequest of £15,000 for the purpose, and recently the hospital was formally opened by the sister of the donor. Broomley House, with its surrounding grounds, was purchased by the trustees last year, and the necessary additions and alterations to convert it into a hospital were made with the advice and assistance of Colonel D. J. Mackintosh, of the Western Infirmary, Glasgow. At the opening ceremony Colonel Mackintosh said that the original building with the necessary additions provided a complete cottage hospital. So far as the cost was concerned, it compared very favourably with any similar institution and was equal to the best of its kind for working. The wards were of ample cubic capacity and adjoined the fully-equipped operating theatre, so that service was reduced to a minimum. The children's ward, with its balcony in front, was furnished with four cots and there was a large room which could be used for private patients.

Births and Deaths.

The monthly return of the Registrar-General for 16 of the principal burghs records a birth-rate of 22·8 per 1000, less by 1·4 than the corresponding month of last year; the rate was highest in Hamilton, Motherwell, Glasgow, and Greenock; lowest in Kirkcaldy, Clydebank, and Dunfermline. Of the 4636 children registered during the month, 301, or 6·5 per cent., were illegitimate, the proportion, as usual, being high in Edinburgh. The death-rate for the burghs was 11·7 per 1000, being 0·4 higher than the corresponding month of last year, and varying from 14·7 in Paisley down to 7·7 in Dunfermline. The deaths of children less than 1 year old numbered 313, equivalent to an infant mortality-rate of 65 per 1000 births; the local rate was 119 in Paisley, 79 in Greenock, 76 in Aberdeen, and 74 in Glasgow, down to 14 in Dunfermline and 29 in Ayr. Deaths from epidemic disease numbered 156, including 1 from enteric fever, 25 from measles, 15 from scarlet fever, 52 from whooping-cough, 21 from diphtheria, and 42 from the diarrhœas of childhood. The influenza deaths numbered only 17, having fallen from 43 in May and 28 in June. Deaths from encephalitis lethargica numbered ten, as compared with 22 in June and 24 in May.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Free State and the Medical Register.

THE Medical Bill, promoted by the Government of the Irish Free State in the Oireachtas, of which mention was recently made in THE LANCET (August 2nd, p. 235), has been somewhat unexpectedly postponed to next session. The Minister in charge of the Bill, speaking in the Senate, said that the information that he had received was that the General Medical Council desired to have a little more time, and they proposed not to introduce legislation in Britain until October. They had previously, at a conference, decided to introduce legislation corresponding to the Bill before the Senate, and have it passed before the summer recess. They now intimated that they could not get the measure introduced, and they would hold it over until October, and would not interpret those Acts as they had previously done. Medical students would continue to come under the operation of the General Medical Council and would be registered until this matter was again taken up.

Sir Patrick Dun's Hospital.

The friends of Sir Patrick Dun's Hospital have been engaged in an intensive campaign to raise funds for the rebuilding of the hospital. The present edifice is more than a hundred years old, and is incapable of being rendered adequate for present requirements, so that the governors are forced to consider the question of rebuilding. They are, however, sympathetic with the suggestion of amalgamating their hospital with several of the other smaller hospitals of Dublin, and they pledge themselves not to proceed with building until they have had a full consultation with the authorities of other hospitals to discuss the easibility of carrying through a scheme of amalgama-ion. There is no doubt that more efficient service ould be rendered to the public if five of the smaller ospitals on the south side of Dublin were to unite. It is known that the staffs of these hospitals are rongly in favour of amalgamation, but a considerable apital outlay will be necessary.

A Short Strike.

A strike of the municipal workers in Dublin and the suburbs took place recently, which, if it had been prolonged, might have had serious effects on the public health. The municipal authorities had discussed the propriety of making a cut in wages in September, and although no decision had been made the workers withdrew their labour. For several days refuse was not cleared away, and for a night or two public lighting was stopped. Fortunately, there was no interference with the water-supply. During the cessation of lighting the strikers made arrangements that the supply of electricity to bakehouses and hospitals should not be interrupted. The strike was settled before there was a general interruption of the industries dependent on electric supply.

Neglect of Vaccination.

For many years past there has been an almost complete neglect of vaccination in many parts of Ireland. This was in part due to the inertia of the late Local Government Board, and in part to a campaign against vaccination. The Ministry of Local Government is now stirring and the attention of the local authorities is being drawn to the necessity of enforcing the vaccination laws. The worst area is in the south-east, Wexford and neighbouring counties, a district in which the propaganda against vaccination has been most vigorously pressed. Of one sanitary district the medical officer reports: "No vaccinations done during the half year; parents had altogether discontinued bringing their children to be vaccinated." Of another it is reported: "The people don't believe in vaccination." In Camolin district, in Co. Wexford, there has been practically no vaccination since 1910. In a neighbouring district vaccination has not been availed of for some years past. The medical officer of Wexford reported that three years ago there were 1406 defaulters, and no vaccinations had been done since. In Bridgetown the only persons who get vaccinated were intending emigrants. In the Navan district of Meath out of 287 children born in the last three years only nine had been vaccinated. In none of the cases has the local authority taken any steps to enforce the law. It looks as if the Ministry will have some trouble to render the population protected against small-pox.

Dublin Hospital Sunday Fund.

At the annual meeting of the Dublin Hospital Sunday Fund held last week it was stated that a sum of £4200 had been distributed among the participating institutions.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Recent French Vital Statistics.

THE medical authorities in France have been unable to publish all the vital statistics for the years subsequent to 1918, but thanks to the courtesy of Mr. A. Moine, of the Comité National de Défense contre la Tuberculose, I have been able to obtain some instructive figures dealing with the period 1918–23. In a table showing the tuberculosis mortality of 53 departments with a population of 25 millions, it is instructive to note how greatly the tuberculosis mortality varies in different places. Thus, in the Department of the Marne there were only 2·51 deaths from tuberculosis per 10,000 persons, whereas in the Department of the Rhône this rate was as high as 38·6 per 10,000. Mr. Moine has also conducted a study of the incidence of tuberculosis in the various districts of Paris, and he has again found that it is extraordinarily patchy: it is endemic in some quarters and hardly known in others. But Mr. Moine sees good grounds for hoping that, by the systematic eradication of the foci of infection, and by improved housing, much can be done to stamp out the disease, which is obviously not so migrant and infectious as epidemic encephalitis and many other diseases. In 1918 there were 293 deaths from pulmonary tuberculosis per 100,000 persons in Paris. Since then there has been an almost uninterrupted decline, and the corresponding figure for 1923 was only 231. Cancer, on the other hand, has risen from 115 deaths in 1918 to 123 deaths in 1923 per 100,000 in Paris. Deaths from typhoid fever have fallen from 5 per 100,000 in 1918 to 0·7 in 1923. In the same period there has been a decline from 8·7 to 1·6 in the deaths from measles. Scarlet fever also shows a decline in the same period from 1 to 0·3. Whooping-cough has declined from 10·5 to 0·6 deaths per 100,000 living persons, and the decline in the diphtheria death-rate is from 4·5 to 0·5. Turning from the Parisian to the general French death-rates, it is interesting to note that between 1919 and 1923 the general death-rate in France has fallen from 19 to 17 per 1000 inhabitants. The infant mortality-rate per 1000 living births has declined from 119 in 1919 to 96 in 1923. In 1922 this rate was as low as 85 per 1000 living births. It is evident from these statistics that within the short period of five years there has been a great advance in the health of the French nation as measured by the most prevalent diseases and the total death-rate, and valuable alike whether France counts her children as “souls” or “bayonets.”

Hygiene and Confectionery.

Although there exists a law in Paris forbidding the sale on open stalls of such articles of food as are consumed without subsequent cooking, this regulation is in effect a dead letter, and recently the Société de Médecine Publique et de Génie Sanitaire has urged a more vigorous application of the law. It is further insisted that more adequate steps be taken to prevent contamination of food exposed for sale in the interior of shops where the constant stream of shoppers brings with it the dust and dirt from the street. This applies particularly to ham and beef shops and to confectioners' displays. Another important question concerns the wrapping up of sweetmeats by hand before they reach the retail trade. This process is often carried out in their homes by employees, adults and children, without any sanitary supervision. One hesitates to think of the possible conditions obtaining in many overcrowded and dirty homes, and the Société rightly demands that this practice shall cease, by forbidding the wrapping up at the worker's home of any edible substance not intended to be cooked.

Hospital Care of Weakly Infants.

At the Hospice des Enfants Assistés, under the control of Prof. Marfan, the mortality among infants under 1 year old was 30 per cent. during the year 1922. This percentage represents a slightly lower figure than in previous years, and is definitely less than the average mortality in hospital creches, which generally exceeds 10 per cent. Dr. Pierre Vallery-Radot, who gave these statistics in a communication to the Academy of Medicine, rightly considers that this figure is too high. As half the number of deaths are due simply to a general state of weakness, he holds that the mortality could be reduced through the organisation of an efficient hospital service for weakly children. The necessary steps would be taken to secure suitable conditions, such as good accommodation under the best conditions of temperature and ventilation, and proper feeding for the weakly infants. He has also outlined measures to provide for breast-feeding, and further to aid in recruiting wet-nurses.

Tuberculous School Teachers.

Tuberculosis among male and female teachers in free schools as well as in public schools may frequently have dangerous consequences for the pupils, whose health ought to be protected against such a risk. On the motion of Drs. Parisot and Violette, the Society of Public Medicine has issued a demand that school teachers and all the school auxiliary staff should submit to a periodical medical examination. Those who show tuberculous lesions already active or likely to become so are informed that they should undergo special examination as frequently as possible. As soon as there is evidence that any risk is being run by the pupils, the affected member of the staff should be given leave from duty or dismissed. To counteract the pecuniary distress which such regulations will entail, the Society demands that reasonable compensation should be made to ensure adequate medical treatment for the affected person, and to provide for his or her family. With regard to the staffs of private schools, this question requires further investigation.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Indications for Operation in Cholelithiasis.

Dr. Károly Engel recently dealt with this subject in a post-graduate course of medicine at the University of Budapest. He said that he was convinced, and his conviction was supported by other clinicians, that cholelithiasis showed a strong tendency to spontaneous healing, in distinction to appendicitis and nephrolithiasis. Healing, of course, was not complete: the gall-stones remained in the gall-bladder, and considerable changes remained permanently in its wall, and it was even possible that the gall-bladder became in some way short-circuited, but clinically the patient recovered and could do a day's work in comfort. In thousands of cases, he held, nature overcame gall-bladder infection without surgical interference, although the process varied greatly with regard to the time required, and it was only when nature failed and sudden acute complications set in that recourse to surgery was justified. On the other hand, it was not advisable to postpone surgical measures until the patient was in a weak state. That this was the general consensus of opinion on the subject was further exemplified by the conclusions reached with regard to this question at the Italian Surgical Congress held recently, where the indications for operation were tabulated as follows: Operation for the removal of gall-stones must be performed (1) in all cases where peritonitis or sepsis threatened; (2) in all chronic cases where the presence of a stone in the bile-duct was shown either by continued icterus or by symptoms pointing to prolonged infection, such as intermittent fever, rigors, emaciation, &c. On the other hand, operation was not allowed (1) in acute cases if a normal resolution could be expected; (2) in chronic cases where attacks of biliary colic occurred at infrequent intervals only, and where stones were voided frequently; and (3) if therapeutic measures—diet, drugs, and baths—were capable of producing lasting improvement. Surgical interference was further sanctioned when continued and severe attacks of colic tended to undermine seriously the patient's constitution, or where such conditions as hydrops or empyema of the gall-bladder were diagnosed.

The Treatment of High Blood Pressure by Sulphur Injections.

Dr. Rusznyak István, assistant physician at the medical clinic of Prof. Koranyi, has found by experience that the irregular occurrence of high blood pressure can be treated with lasting effect by exhibiting sulphur solutions by the intra-muscular route. The procedure is as follows. The first injection of 1 c.cm. of sulphur solution, containing 0·001 g. sulphur, is made in the gluteal region, followed by a second after two or three days; thereafter, at longer intervals, the subsequent doses are gradually increased to 5 or as much as 10 c.cm. of the solution. The injections are admittedly painful, and are generally accompanied by pyrexia, which is apparently beneficial. It has been observed that other artificially produced conditions of fever do not have a lasting effect in reducing high blood pressure. In the majority of cases four to five injections are sufficient for the course of treatment, even if the blood pressure were not completely reduced to the normal level. If necessary, the course can be repeated after several weeks. It was noted as a striking fact that when the necessary course had been completed, and the concomitant reaction had developed, the blood pressure remained at a considerably lower level with a marked degree of permanence. At the same time, the symptoms of headache, vertigo, and pseudo-uræmic manifestations were mitigated, if not, as in some cases, completely abolished. The effect of the sulphur seems to be to check spasms of the arteries, and to inhibit the development of such angio-spasms.

Deep Antisepsis of Wounds.

Dr. Eugen Polya, professor of surgery at the University of Budapest, recently discussed the method of obtaining antiseptic conditions in the deeper tissues of wounds. The method consists in infiltrating the tissues surrounding the wound with a solution of vuzin, in the strength of 1 in 10,000, or with a solution of rivanol, in the strength of 1 in 4000. Some surgeons commend this method highly, while others show less enthusiasm for it. Prof. Polya gave the method a thorough trial, and came to the conclusion that, for the present, he could not recommend it, as if it were not properly administered it might lead to untoward consequences. He admitted that he favoured cautious medical progress only, and would not be disposed willingly to advocate a novel method which introduced an added and superfluous danger to the patient, especially when the old method of antisepsis on the recognised physical basis of thorough opening of the wound and drainage gave such good results. He attributes much importance to the thorough application of iodine to the wound cavity, and, if the wound has been contaminated by earth, then irrigations with vuzin and rivanol prove efficacious. If the wound cannot be perfectly healed with iodine, he maintains permanent irrigation of the wound by Dakin's solution. He has a marked preference for treating a wound, in the first instance, with hydrogen peroxide before the application of iodine; and when it is possible to expect healing by first intention the iodine is omitted altogether. Here irrigation of the wound with rivanol is of value. In earth-soiled wounds it is important to give a prophylactic injection of antitetanic serum, and if the patient is a diabetic then insulin must be administered.

"Audi alteram partem."

THE VIRUS OF FOOT-AND-MOUTH DISEASE.

To the Editor of The Lancet.

Sir,—Your Dutch correspondent in The Lancet of June 28th, page 1330, states that a committee of six appointed by the German Department of Agriculture was supplied with subcultures of the *Loeffleria nevermanni*, and that I, as a member of this committee, was able to state on May 19th last that the infection tests with this material gave positive results. The explanation which I actually gave on this date was as follows:—

> "... Herr Dahmen has carried out before the Commission infection experiments with a 6 and with a 26 generation culture. The culture labelled Generation 6 produced in the guinea-pig immediate as well as delayed formation of vesicles, whereas the culture labelled Generation 26 led only after repeated inoculation from guinea-pig to guinea-pig, in the manner described by Dr. Dahmen, to the formation of vesicles. ..."

The successful inoculations were thus carried out, *not* by the Commission with any kind of material, but by Prof. Dahmen himself in his own laboratory. Up to the present the Commission has not been able to produce infection with "cultures" made on Dahmen's method, nor with "cultures" which they received at the end of July from Dr. Dahmen himself. The work of the Commission is not yet complete, and the point is up to the present not fully cleared up whether the so-called cultures actually consist of living micro-organisms.

I am, Sir, yours faithfully,

F. K. Kleine.

Berlin, N. 39, August 13th, 1924.

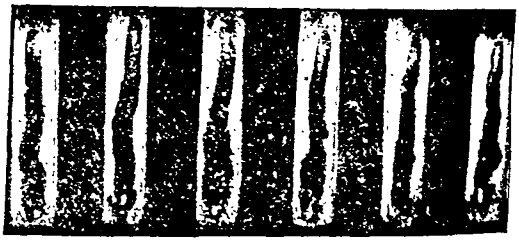
THE CLINICAL THERMOMETER AS A CARRIER OF INFECTION.

To the Editor of The Lancet.

Sir,—The following experiments were undertaken to determine whether the clinical thermometer, having been used in the mouth of one patient and then washed in tap water and dried on a clean towel, is capable of conveying bacteria to the mouth of another patient. It is not for a moment contended that this is the method of cleansing adopted by every medical practitioner, but it is maintained nevertheless that this is a procedure of everyday occurrence. Surely there are few people who have not seen the thermometer taken from the patient's mouth, washed in water, either in the bedroom jug or in a tumbler, dried on a towel, and replaced in its case.

In order to test the efficacy of this method of cleansing, some saliva was placed in a tube and to this a small portion of a culture of *B. prodigiosus* was added, and in this mixture clinical thermometers were placed.

In the first experiment, after being infected in this way, the thermometer was well rinsed in a jug of tap water in which it was briskly moved backwards and forwards 20 times; it was then wiped by drawing it through a clean piece of cloth, firm pressure being exerted between the finger and thumb holding the cloth, the cloth was then folded over and the process of wiping repeated. The thermometers were placed in tubes containing sterile broth in which they were well rinsed. These tubes were incubated for six hours and from each a culture on to a nutrient agar slope was taken; this was incubated overnight and then left at room temperature.



Cultures from clinical thermometers, infected with *B. prodigiosus*, which have been washed in water and wiped with clean cloth.

The result of the above was that in 12 observations, using six different clinical thermometers, a culture of *B. prodigiosus* occurred in each case.

As washing the thermometer in the way above described does not result in removing the infecting bacteria, in the next experiment the thermometers were washed in a stream of tap water, being held in the running water for 30 seconds. In 12 observations, however, *B. prodigiosus* cultures were obtained in each case.

Three more observations were made in running tap water for 60 seconds and a further three for three minutes, the thermometers being wiped as previously described, after being held under the tap. Cultures of *B. prodigiosus* were obtained in each case. In order to avoid the faint possibility of the tap water or the pieces of cloth, on which the thermometers were wiped, being contaminated with *B. prodigiosus*, three cultures of tap water and three cultures from the samples of cloth used were made, but in no instance was the organism recovered.

The remedy for this appears to be obvious; but in order that the method of cleansing may be satisfactorily carried out, the help of the instrument-maker is needed. First, we must have his assurance that the markings on the thermometer will resist prolonged immersion in a reliable antiseptic; and secondly, a suitable case is necessary which will hold the antiseptic fluid and thermometer and ensure that no leakage can occur in the pocket. It is scarcely necessary to state that the addition of a small amount of antiseptic to the water in which the thermometer is rinsed in this manner is not sufficient for the purpose, for, if carbolic acid is used, five minutes is the bare minimum time in which a thermometer which had been infected with *B. typhosus* could be disinfected if the concentration of carbolic acid was only 1 per cent.

The photograph shows the cultures of *B. prodigiosus* obtained after "cleansing" the thermometers in the manner here described.

PUPIL MONEY: AN UNPUBLISHED LETTER FROM JOHN HUNTER.

To the Editor of The Lancet.

Sir,—These two letters fill a gap in Dr. G. C. Peachey's excellent Memoir of William and John Hunter (see p. 376). They were given to my father, Mr. Henry Power, on Oct. 24th, 1888, by Mr. Charles Hawkins, who says in a covering letter, "There is no doubt that Hunter was not entitled to more than one-fourth share of the fees. This is clear from the letter of Mr. Williams which I enclose: you may keep it, and there are not many letters extant from a pupil of St. George's Hospital at its foundation in 1733. Hunter was not ungenerous. I believe he only meant in claiming the extra fees to use a *rough* threat to induce his colleagues to work harder at the hospital. I think *his* letter I enclose—which you may also keep—goes to show this."—I am, Sir, yours faithfully,

D'Arcy Power.

Chandos-street, W., August 16th, 1924.

1. *From John Hunter, to the Surgeons at St. George's Hospital.*

Gentlemen,—On Monday I sent you a letter the purport of which I need not mention; and on the same day a Gentleman enter'd with me for 6 months; altho' the time of settling was past, and therefor whoever enter'd was to be brought into the next quarter; yet to prevent even a shadow of suspicion that I might have keeped back the Gentleman's entering till the quarter was over, I have sent the three shares. This is a mere point of delicacy, and unnecessary, if every Man acted upon strictly honorable terms. I am, your obed^{t} Serv.,

John Hunter.

Leicester Sq^{r}.
July 11th, 1792.

The letter is addressed to Messrs. Gunning, Walker, and Keate, St. George's Hospital. It is docketted: "Mr. Hunter's Letter to the Surgeons of the Hosp^{l}. 11th July, 1792."

2. *From Mr. Thomas Williams to Mr. John Gunning.*

Sr.—As you desire me to inform you what was the Custom at St. Georges Hospital respecting the division of the Pupil Money arising from the attendance of the surgeons Pupils there in my time; I must declare that I remember well from its first Institution in the years 1733, 1734 & 1735 to the year 1739 and later when I attended as an apprentice to Mr. Wilkie, the money arising from the Pupils in Common, and from the apprentices paying as Pupils in particular was equally divided amongst the surgeons; and that I remember likewise that the Surgeons Pupils were never considered as belonging to any particular Surgeon but as Pupils at large to the Hospital and under the Direction of all the surgeons alike.

I am S^{r}.
Your most Obd^{t} Servant,
Thos. Williams.

Queen Street, Soho Square, Nov^{br} 27, 1792.

Addressed: John Gunning, Esq^{r}. Docketted: "Mr. Williams, Surg^{n} Lock Hospital, to Mr. Gunning, 27th Nov., 1792."

"CANCER: HOW IT IS CAUSED, HOW IT CAN BE PREVENTED."

To the Editor of The Lancet.

Sir,—With reference to your comments on a letter, with this title, in your issue of July 19th concerning the incidence of cancer in uncivilised races, my surgical work for the past 22 years has lain in the Punjab amongst a people primitive as to their diet, though I should hesitate to describe them as uncivilised. An inquiry into the prevalence of cancer amongst this people conforms with some of the statistical postulates contained in your note: (1) Is known accurately. (2) Sufficiently accurately for a comparison of the sort in view. (3) The annual reports of the Inspector-General of Civil Hospitals, Punjab, deal with over 6,000,000 attendances of out-patients, and operations run to a quarter of a million yearly. A large proportion of the total number of these operations are for the relief of senile cataract, so it is unnecessary to labour the point that many people survive until the "cancer age." (4) A large number of post-mortem examinations are held in Government mortuaries in criminal and police cases. Facilities exist for microscopical examination of morbid tissues.

The diet of this people is, I think, worthy of attention. It is very simple, and owing to caste injunctions and inhibitions and economic causes very constant—probably the diet of no people in the world varies less from that of their ancestors of 6000–8000 years ago. Briefly, it consists of lightly scorched unleavened bread, made from a dough of wholemeal stone-milled unsifted flour into flat cakes about the size and shape of our pancakes. This "bread" is eaten with dâl, a sort of pulse, or with curried vegetables, and large quantities of cellulose are taken in the form of raw radishes, sugar-cane, cucumber, and raw fruit, according to the season. The peasants also drink quantities of milk as they are great breeders of buffaloes and kine. With them bread *is* the staff of life; this coarse, whole-meal, unleavened bread and dâl is the daily fare of millions from the time they leave their mothers' breasts until they die. They have magnificent teeth and are usually of fine physique; to see a crowd of Sikhs stripped to their loin-cloths for a village faction fight is a sight for sore eyes.

Finally, they appear to be singularly immune to cancer in any of its forms. The kangri cancer described by Neave in Kashmir I have never seen in the Punjab, though severe scarring from burns is common. I have never seen a case of betel-nut cancer, such as described by Spittle in Colombo, and by others in Southern India, though the practice of chewing betel-nut is common in the Punjab. I have never seen a case of cancer of the penis, though I have frequently had to amputate the entire organ while in the Himalayas for ulcerating granuloma of the pudenda; none of these proved to be cancerous on microscopical examination. In the course of my 22 years' service I must have made many hundreds of post-mortem examinations, but I have never come across a case of latent cancer. I cannot remember a case of cancer of the tongue in the whole of my 22 years' service. It must be distinctly understood that the foregoing statements apply only to the unsophisticated Punjabi and Himalayan villager, who cultivates his own fields—not to the upper and educated classes or even to the lower orders of the large towns.

It is difficult to avoid the conclusion that cancer is relatively uncommon in this class of the population, though cancer in all its forms is frequent amongst Europeans and Anglo-Indians in India.

I am, Sir, yours faithfully,
H. HALLILAY,
Lieut.-Col., I.M.S.; late Civil Surgeon, Simla.
August 14th, 1924.

FUNDAMENTAL CANCER RESEARCH.

To the Editor of THE LANCET.

SIR,—I have read with interest in your issue of August 9th a reference to the fourth instalment of the summaries issued by the Departmental Committee on Cancer and sent out by the Ministry of Health, but I think that the statement made by the Committee that "No constant signficant differences [in cancer metabolism] have been discovered" is too sweeping, and is not borne out by the work that has been done in the research department of the Glasgow Royal Cancer Hospital.

Thirteen years ago[1] I published a paper upon the Rôle of Fat in the Ætiology and Progress of Cancer, and in that I pointed out that a large increase of the unsaturated fatty acids takes place in cancer patients, the percentage rising from 62·1 in health to 72·6 in that disease. Further investigations upon this point have been conducted by Mr. A. N. Currie, biochemist in the research department, who has recently published an article[2] on the Fat of Adipose Tissue in Malignant Disease. In it he not only confirms the presence of an excess of unsaturated fatty acids, but he has shown that this excess is more marked in the vicinity of the cancerous tumour than elsewhere. Further, his paper brings out that there is a qualitative difference in the fat of the cancerous patient compared with that in health. Not only is the unsaturation of the fat more marked, but there is a difference in its pigmentary constituents. It is not easy to say what exactly this unsaturation indicates, but of its presence there can be no doubt; so that, on these grounds, I think that it is scarcely correct to say that no constant significant differences have been discovered.

One possible explanation of this condition is that a local enzyme may be the cause of this unsaturation, so that the fat may form an easier pabulum for the cancerous growth. Of the great emaciation that marks the condition of the cancerous patient in the last stages of the disease, the cases in the Glasgow Royal Cancer Hospital afford ample proof, and they are a striking example of the marked change in the body metabolism when cancer is present.

I am, Sir, yours faithfully,
GEORGE THOS. BEATSON, M.D.
Woodside-crescent, Glasgow, W., August 12th, 1924.

PAROXYSMAL RHINORRHŒA AND BRONCHIAL ASTHMA CAUSED BY STRAW.

To the Editor of THE LANCET.

SIR,—Though it is probable that several different conditions are still included under the term bronchial asthma, much has been learned of its ætiology, especially in relation to anaphylaxis. It is sometimes possible to identify the antigen so definitely that we may successfully screen the patient from contact with it.

A clerk, aged 19, had suffered only from the usual infections of childhood and never experienced any symptoms relating to the nose or lungs until two years before coming under our observation. It was then that he was engaged to work at an ironmonger's store. He soon found that almost every day he had sudden attacks of nasal obstruction, with a watery secretion and much sneezing. At the same time he became short of breath, even when he was at rest. Itching macules often appeared on his arms if he left them bare. Whenever he was away from the store, as on Sundays and holidays, he was free from attacks. When at length he came under our observation and was closely questioned, it became evident that attacks only occurred when he had unpacked china packed in straw. On physical examination he appeared strong and the heart and lungs were normal. The mucosa of the inferior conchæ of the nose was hypertrophied.

Some of the straw used in packing was extracted with decinormal sodium hydrate. With the extract a cutaneous reaction was performed on the ulnar side of the forearm. In five minutes a vesicle appeared 5 cm. higher up the forearm and soon became large. The patient declared that it was like the vesicles he was wont to get. No other eruption appeared, not even on the spot where he was scratched. With his permission we inserted into one of his nostrils a pledget of cotton-wool steeped in the straw extract. In 5–10 minutes a severe paroxysm of rhinorrhœa began, with swelling of the mucosa, watery secretion from the nose and the conjunctivæ, itching, and sneezing whereby the cotton-wool was blown out. The attack was over in a few minutes, and asthma did not occur, perhaps because the cotton-wool had come away.

He was excused from the work of unpacking and no further attacks have occurred except on two or three isolated occasions when he has had to do this particular work.

We are, Sir, yours faithfully,
G. FLÖYSTRUP, M.D.
Copenhagen, August 16th, 1924. JENS KRAGH, M.D.

THE GROWTH OF OCCUPATIONAL HYGIENE.

To the Editor of THE LANCET.

SIR,—The figures given by Mr. A. H. Southam and Dr. S. R. Wilson of the large number of mule-spinners treated for scrotal epithelioma in the Manchester Royal Infirmary, followed by Dr. S. A. Henry's inquiry into the distribution of these cases in the cotton mills of Oldham (59), Bolton (21), Preston (17), Blackburn (14), and other Lancashire towns in smaller number, has led to a startling result. A case was brought in a Lancashire court, and, after being argued fully, £2000 was awarded by the judge in compensation. Naturally the decision has created great interest in Lancashire. The case will probably go to the High Court, where we shall be told whether this decision will stand or not. But as it stands the result of a piece of careful clinical research on industrial life is already great. Such a decision, if upheld, should do much to encourage all those who, throughout the country, are striving to prevent disease. Some day we may get a method which will decisively link a case of pulmonary tubercle to the house in which it was contracted. Then, if the house was provided for him by an employer and if the judge can be persuaded that the man thus became infected in the course of his employment, compensation will become payable to the patient or his representative. This will become a haunting fear for employers of labour, of domestic servants, of sailors, even of soldiers, all of whom will then begin to do their best to avoid for their employees the risks which medical officers of health have long been forecasting. These officers should find that their proposals are received in future with more cordiality than hitherto they have experienced, once it becomes realised that a subsequent scientific discovery may involve back payment of compensation, if it succeeds in explaining the origin of a disease to-day thought to be constitutional as really depending definitely on employment. It looks as though the time may be coming when employers will come and beg the medical officer of health to tell them what more they can do to keep their men healthy.

I am, Sir, yours faithfully,
SPERO DUM SPIRO.

Obituary.

GEORGE HEATON, M.B. OXF., F.R.C.S. ENG.

THE sudden death of Mr. George Heaton, honorary surgeon to the General Hospital, Birmingham, at the age of 63, has caused the deepest regret not only to members of the medical profession in the Birmingham district, but to a large number of private friends and past patients. Mr. Heaton was educated at Clifton School, of which he became head boy, and proceeded thence to Oxford with a demyship to Magdalen, where he attained a first class in the Natural Science Tripos. He then became a student at St. Bartholomew's Hospital, where he had a brilliant career, winning the Senior Entrance Scholarship, the Brackenbury, and the Lawrence Scholarship and Gold Medal. He qualified M.B., Ch.B. in 1888 and became house surgeon to Mr. Willett. In 1890 he was elected resident surgical officer to the General Hospital, Birmingham, and so returned to his native city. This post is usually a stepping-stone to membership of the staff of the hospital, and so it proved in Heaton's case, but whilst holding it he suffered the misfortune of an infected wound, which threw a shadow over the rest of his life, and in some degree lowered his general health and vitality, so that he always carried on his work with a certain reserve, and his early brilliant promise was not fulfilled as it would have been under other conditions. Elected to the staff of the General Hospital as assistant surgeon in 1891, he became surgeon in 1894 at the unusually early age of 33, in some ways a fortunate circumstance for him as he had the opportunity of developing a dexterity in operative work not so easy to acquire at a period, say, ten years later. By the laws of the hospital members of the staff have to retire at the age of 60, or when they have held office for 25 years. As a result Heaton was retired at the age of 58, in the fullness of his power, a real loss to the service of his hospital. In addition to being a clinical lecturer in the University, in his earlier days he was demonstrator of surgical pathology, assistant to the chair of surgery, lecturer in operative surgery for 11 years, and a clinical examiner in surgery.

Apart from the run of general surgical work, Heaton was more attracted to abdominal surgery than to other fields, and he published several valuable papers on abdominal work. He was a very good diagnostician, a careful and skilful operator, concerned above all things in bringing his patient safely through his ordeal, never sacrificing safety to some brilliant ideal with attendant greater risks. As a teacher he was thoroughly sound, clear, and concise—painstaking to a degree. His alma mater recognised his worth by making him an examiner in surgery at Oxford. Heaton took his share in all that concerned the medical life of the city, the medical societies, and the Medical Institute, but always his greatest interest was in the hospital which he served so well, and when he retired he received a presentation of silver from those intimately acquainted with the work of the institution. He was always a most excellent colleague, but he often held views with tenacity, and argued stoutly for them. Once an adverse decision had been arrived at, however, he loyally accepted it, and there was no loss of harmony. He will long be kindly and affectionately remembered by those with whom he worked, in whatever capacity they served.

His unexpected death followed a prolonged attack of phlebitis, from which he appeared to have recovered as he had partly resumed active life again.

ANDREW SMITH M.D. EDIN.

THE sudden death occurred from syncope on August 1st of Dr. Andrew Smith, of Whickham, Durham. Born in Leven, Fifeshire, he received his medical education at the University and at the Royal College of Surgeons of Edinburgh, and graduated M.B. with honours at the University in 1876, obtaining the M.D. five years later. He took up practice on qualification at Whickham, where in the following years he built up an extensive practice and won the respect and esteem of a large circle in the district. He kept himself abreast of medical progress and was a prominent figure in all local medical societies, having for a time held the office of President of the Northumberland and Durham Medical Society, also of the Newcastle-on-Tyne Clinical Society, and when these two amalgamated as the Newcastle-on-Tyne and the Northern Counties Medical Society he retained an active interest in their work. He was a member of the Society of Medical Officers of Health, and had acted as President of the Northern branch, and was medical officer of health to the Whickham Urban District Council until his death. He was keenly interested in the ambulance movement, and to his practical help the Whickham District War Memorial Hospital owes in no inconsiderable extent its foundation, while under his guidance as hon. medical officer the hospital became a thoroughly up-to-date and valuable institution. Dr. Smith was a prominent figure in the British Medical Association, of which he was a member for 41 years, and filled successively the offices of chairman of the Newcastle-on-Tyne division and President of the North of England Branch. Dr. Smith was also for a time President of the Edinburgh Graduates' Association in Newcastle. He leaves a widow and a family of four sons and three daughters. Three of his sons are in the medical profession and assisted their father in his practice. To his family we express our heartfelt sympathy in their loss.

CHARLES RITCHIE NIVEN, M.B., C.M. GLASG.

Charles Ritchie Niven, who died from heart failure at his residence, Everton, Liverpool, on Monday, August 18th, was 62 years of age. He qualified at Glasgow in 1888 and went to Liverpool 30 years ago. For the last three years he had been honorary secretary of the Liverpool Panel Committee. Dr. Niven was the founder and a very active worker in connexion with the Everton and District Medical Association. He leaves a widow and two daughters.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. W. H. Butcher to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Col. J. C. Connor, on attaining the age limit for compulsory retirement, is placed on retd. pay.

The undermentioned Lts. are confirmed in their rank: C. R. Christian, R. J. Rosie, J. Huston, and E. G. Dalziel from Gen. List, T.A.

ARMY RESERVE OF OFFICERS.

Col. E. M. Morphew, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

F. C. Lewis to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. F. Evans (late R.A.M.C., T.F.) to be Capt.

FOREIGN MEDALS.

The following have received from the President of the French Republic medals for services rendered during the war:—

Médaille de la Reconnaissance Française.

En Argent.

Captain Alfred Sigismund Bruzaud, R.A.M.C. (T.F.) (now retired, Territorial Army); Temporary Captain Simon John Coulter Fraser, R.A.M.C.; Temporary (Honorary) Major Louis Francis Knuthsen, R.A.M.C.; and Quartermaster and Captain John Hannaford Maunder, R.A.M.C. (Territorial Force).

En Bronze.

Captain Lionel Thomas Challenor, R.A.M.C. (T.F.); Temporary Captain Richard Bertram Johnson, R.A.M.C.; and Temporary Captain Frederick Alexander Ross, R.A.M.C.

a difficult abdominal operation. He obtained apparently excellent relaxation by this means. The anæsthetist was completely under his control, moving the indicator on the machine according to directions. This demonstration was a pleasure to watch, and the surgeon was an expert, not only at his own job, but as an anæsthetist. He realised the supreme importance of gentleness in handling the parietal peritoneum, and during the whole operation never made a single rough or unnecessary movement. There was a supply of ether in the bottle attached to the machine, but it was not used.

I saw very few students giving anæsthetics under tuition, and these were chiefly in Canada. The so-called interns, corresponding to our house officers, do comparatively very little anæsthetic work. There is, in fact, not the same reason for them to do so, as all surgery is done in hospital to which there is attached a team of full-time salaried assistants.

AN ASEPTIC METHOD OF TYING SUTURES.

IN a recent number of the *Medizinische Klinik* Dr. Franz Weigl, of Vienna, describes a useful practical method of tying sutures without touching the material with the fingers. The advantages of such a procedure are obvious where the surgeon is chary of risking sepsis by handling the wound at the end of the operation. The method, which is very simple and which enables the knot to be tied just as quickly as by hand, is as follows: After the needle in the needle-holder has been passed through the edges of the wound the end of the suture, A, is grasped by a pair of artery forceps. The needle is removed from the suture by the needle-holder and laid aside, then the end A, which is held by the artery forceps, is twisted once round the needle-holder (Fig. 1). The needle-holder then picks up the other end of the suture (B, Fig. 2). While the artery forceps maintains its grip of end A the needle-holder containing end B is withdrawn through the loop, the whole is pulled tight, and in this way the first tie of the knot is made. Then end A is released by the artery forceps and the end B twisted round the artery forceps, which now seizes end A, draws it through the loop, and thus completes the knot.

FIG. 1.

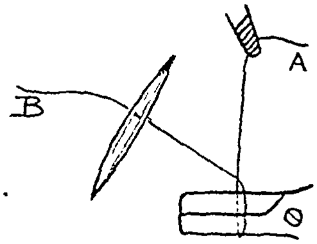

FIG. 2.

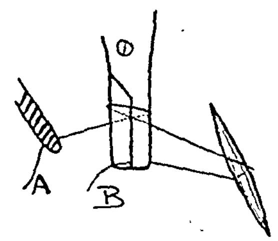

SANTONIN IN HOOK-WORM DISEASE.

AN OFFER.

To the Editor of THE LANCET.

SIR,—In a leading article on anthelmintics in your issue of July 19th you state that it is probably the economic factor which has prevented the trial of santonin in the treatment of hook-worm disease, and the absence of reports of its action on these parasites is to be regretted. We share your desire to advance scientific research in reliable anthelmintic medicines. Considering the efficacy of santonin against other nematodes, it would be of great interest to have reliable reports of its action on hook-worms. Being sole distributors of santonin and genuine Russian wormseed containing santonin, we beg to inform you herewith that we are prepared to supply interested scientific institutions with such quantities of santonin as they may require for research purposes free of all charge.

We are, Sir, yours, faithfully,
THE EASTERN AND RUSSIAN TRADING COMPANY, LTD.
8, Drapers-gardens, London, E.C.2, August 19th, 1924.

URGENT TELEPHONE CALLS.

To the Editor of THE LANCET.

SIR,—Under this heading in THE LANCET of August 16th your correspondent, "F. W. W.," rightly points out the ambiguity, when taken alone, of the wording at page 4 of the directions for a fire, ambulance, and police emergency call, as given in the London Telephone Directory. These directions, however, end, as "F. W. W." observes, with the sentence "(see Instructional headlines)." If "F. W. W." turns to page 316 he will find under "Fire Brigade" as follows: "In case of Fire call Fire Brigade: no number is required. When Fire Station replies, give address of Fire." Again, on the front, outside covering leaf of the current issue of the Directory, will be found similar instructions, as follows: Call "Fire Brigade," no number required. "When Fire Station replies, give address of fire." From this, it is seen that, in the call, no number whatever is required to be given, but merely the address of place where the fire has occurred. This should be given by the caller to the officer replying from the fire headquarters station, who will then communicate and send on aid from the nearest district fire station.

Whilst on the question of fire prevention I may, perhaps, here mention another important failing, as showing the supreme ignorance of the public in most matters connected with fires—namely, the whereabout of the nearest street fire-alarm to their premises, and how effectively to call up the fire brigade by 'phone. The third failing I refer to is to the effect that, in my experience, few workers or residents give any thought whatever, until a fire actually occurs, to means of escape in such an emergency. As suggested by me in my Warnings against Fire, "It is too late to begin making inquiries when the building is in flames." In connexion with this matter, in giving evidence before the recent Royal Commission on Fire Prevention, I pointed out that, on an average, in every third fire inquest in the City of London, the jury, after a careful personal inspection with experts of the premises, found that the means of escape from fire was inadequate, and fell short of the requirements of the London Building Acts.

I am, Sir, yours faithfully,
F. J. WALDO.
H.M. Coroner for the City of London and Southwark.
August 18th, 1924.

GRATUITOUS MEDICAL ATTENDANCE.

To the Editor of THE LANCET.

SIR,—The profession know only one rule—*not* that of the highwayman, "Your money or your life"—but simply *service*.

My rule is not to charge a fee to any member of the profession (including dentists), his wife, or unmarried daughter.

The clergy should be charged. Because they are poor, marriage is not imperative; they must shoulder the burden of responsibility. The poor clerk, the poor tradesman, the poor professional man, is usually dealt with according to his necessity—the clergy may be no better off, but they are not worse.

When ecclesiastical incomes become proportionate to services rendered, and cathedral dignitaries cease to receive much for very little, *our* hard-worked profession may then consider doing something for nothing for this particular class of professional man.

I am, Sir, yours faithfully,
W. B. COSENS.
Dorchester, August 16th, 1924.

To the Editor of THE LANCET.

SIR,—I always understood that it would be considered unprofessional to charge a doctor or his family for attendance.

Unfortunately my wife had to undergo a gynæcological operation some time ago, which was performed by one of two local men.

In thinking the matter over, I decided to call upon the operator and offer him some kind of a fee as an acknowledgment of his kindness. I was saved this trouble, however, for, before my wife was even sitting up, I received a letter asking for 22 guineas—half fees, he stated—so that I should not be under the necessity of making him a present!

I sent him a cheque by return and placed his letter on the receipt file of tradesmen's bills. Could I have done otherwise? I enclose my card.

I am, Sir, yours faithfully,
CONTEMPT.
August 18th, 1924.

VIBRATORY MASSAGE DE LUXE.

To the Editor of THE LANCET.

SIR,—During the holiday overhauling of London streets there is to be seen this year in large numbers a vibratory apparatus of herculean proportions used for breaking up the concrete of the road—and very efficiently it does its work. What the effect of the noise and vibration has upon the men who wield these things can hardly be imagined, but the vibration is such as to be exceedingly irksome to the passer-by and to residents within 40 or 50 yards of the spot. Has the human element in this business been tested? or are we to wait until clinical notes of functional disorder appear in medical journals and the text-book of industrial medicine records in a few years' time a new occupational disease? Is there no official medical department which can assure the citizen of sensitive conscience that these men are not doing themselves grievous bodily harm in the interest of a community desirous of speeding up its lines of communication?

I am, Sir, yours faithfully,
B.Sc.
August 18th, 1924.

STUDENTS' GUIDE—SESSION 1924-1925.

THE scheme upon which the Students' Number of THE LANCET is constructed will make it easy, we hope, for all who consult it to find what they seek. The General Council of Medical Education and Registration is the controlling authority of all the medical and dental education of the country, and its responsibility for the upkeep of the Medical Register and for the maintenance of the examination standard is first explained. But the student has to be taught as well as examined, and as the systems under which instruction can be obtained do not conform to one pattern, the various curricula are described in detail, and under their respective headings the necessary information will be found concerning the facilities for medical study offered at the different teaching centres of the United Kingdom. The regulations for the examinations, both preliminary and professional, at these centres are set out so that the student desiring to obtain a medical degree from any university, or a diploma from any medical corporation, may ascertain the course of clinical instruction and the conditions under which submission for examination has to take place. The metropolitan medical schools and hospitals are grouped under the University of London, of which they are constituent bodies, although their educational opportunities are offered to students of other universities as well as to those seeking the qualifications of the medical corporations. A similar plan is adopted in dealing with the provincial universities, the hospitals in direct connexion with which are described with the universities; the hospitals may not be official schools of the universities, but they supply an integral section of the teaching required.

Upon securing degrees or diplomas admission to the Register follows, and greater education begins. The prudent young doctor already knows what he or she desires to make the next step, and there is a large range of choice displayed. The inducements to enter one of the Services should prevail more than they have done of recent years. An account is given of the conditions under which commissions can be obtained in the Navy, Army, Indian, and Air Force Medical Services, and in the Colonial Medical Service.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE powers and duties of the General Medical Council, or "General Council of Medical Education and Registration of the United Kingdom" to give the Council its full title, have been set out in detail in many previous Students' Numbers of THE LANCET. It is first a registering body: no person, even though his qualifications have been obtained by examination, is a legally qualified medical practitioner until his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that medical education reaches an efficient standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council at present consists of 38 members, of whom, as will be seen by the annexed list, all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives. There are also three additional members appointed by the Privy Council under the Dentists Act, 1921, under which the powers and duties of the General Medical Council with regard to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the Dental Board of the United Kingdom (see p. 477).

President of the General Council: Sir Donald MacAlister. Members of the General Council: Sir Humphry Rolleston, chosen by the Royal College of Physicians of London; Mr. H. J. Waring, F.R.C.S., Royal College of Surgeons of England; Dr. Benjamin Bloomfield Connolly, Apothecaries' Society of London; Mr. Arthur Thomson, F.R.C.S., University of Oxford; Dr. Wynfrid Laurence Henry Duckworth, University of Cambridge; Dr. Robert Howden, University of Durham; Sir Sydney Russell-Wells, University of London; Dr. Robert B. Wild, Victoria University of Manchester; Sir Gilbert Barling, University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Thomas Wardrop Griffith, University of Leeds; Mr. John Beresford Leathes, M.B., University of Sheffield; Sir Isambard Owen, University of Bristol; and Dr. David Hepburn, University of Wales. Dr. William Russell, chosen by the Royal College of Physicians of Edinburgh; Sir James Hodsdon, Royal College of Surgeons of Edinburgh; Dr. James Alexander Adams, Royal Faculty of Physicians and Surgeons of Glasgow; Dr. H. Harvey Littlejohn, University of Edinburgh; Sir Donald MacAlister, University of Glasgow; Dr. Matthew Hay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore, chosen by the Royal College of Physicians of Ireland; Sir Arthur Gerald Chance, Royal College of Surgeons in Ireland; Dr. Edward Magennis, Apothecaries' Hall of Ireland; Dr. Andrew Francis Dixon, University of Dublin; Dr. Denis Joseph Coffey, National University of Ireland; and Mr. Thomas Sinclair, F.R.C.S., Queen's University of Belfast. Nominated by His Majesty, with the advice of his Privy Council: Sir Francis Henry Champneys, Sir George Newman, Sir Nestor Tirard, Sir Leslie Mackenzie, and Sir Edward Coey Bigger. Elected as Direct Representatives: Dr. J. A. MacDonald, Sir Thomas Jenner Verrall, Dr. Robert A. Bolam, Mr. E. B. Turner, Sir Norman Walker, and Dr. Leonard Kidd. Treasurers of the General Council: Mr. H. J. Waring and Sir George Newman. The three additional members are Mr. William Henry Dolamore, M.R.C.S., L.D.S.; Mr. William Henry Gilmour, M.D.S., L.D.S., and Mr. William Guy, F.R.C.S.E., L.D.S.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

The following are the General Medical Council's Regulations in regard to the registration of medical students which came into force on Jan. 1st, 1923.

Registration of Medical Students.

1. Subject to such exceptions as the Council may from time to time allow, every medical student, at the commencement of his studies, should be registered in the manner and under the conditions hereinafter set forth.

2. Before registration as a student every candidate should produce evidence that he has attained the age of 17 years.

3. The minimum standard of General Education required is that of University matriculation or entrance examination in the Faculties of Arts or Pure Science.

4. Before registration as a student every applicant should be required to have passed an approved examination in general education, and, in addition thereto, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies.

5. A student who has diligently attended an approved course of instruction in elementary biology at a secondary school or other teaching institution recognised by a licensing body may be admitted to the professional examination in elementary biology immediately after his registration as a student.

6. The commencement of the course of professional study recognised by any of the licensing bodies should not be reckoned as dating earlier than 15 days before the date of registration.

7. Every person desirous of being registered as a medical student should apply to the registrar of the division of the United Kingdom in which he is residing, according to a prescribed form, copies of which may be had on application to the several licensing bodies, medical schools, and hospitals, or at the offices of the Medical Council; and should produce or forward to the registrar evidence that he has attained the age of 17 years, that he has passed a preliminary examination in general education recognised by the General Medical Council, and, in addition, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies, and that he has commenced medical study.

Regulations which the Council has prescribed for the maintenance of the register of medical students:—

1. It shall be delegated to the Education Committee to prepare and issue from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are specially recognised by, the General Medical Council.

2. The Council has recognised the undernoted university examinations, subject to the conditions specified below: viz., at Oxford University, Responsions; at Cambridge University, the Previous Examination; at the Scottish Universities, the Preliminary Examination; and the Matriculation Examination at the Universities of Birmingham, Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, and Wales.

3. The conditions prescribed by the Council are:—(1) The standard of the examination shall not be lower than that of the University Matriculation Examinations in the Faculties of Arts and Pure Science. (2) The certificate shall bear evidence that the candidate has passed in the following subjects, viz.:—(*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English. (*d*) An additional subject or subjects, as required by the regulations of the particular examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose.

4. Subject to the conditions specified above (Section 3, Subsection (2)), the Council will recognise all examinations conducted by recognised authorities in Great Britain accepted by one or more of the above-named Universities as equivalent for purposes of Matriculation to an examination named in the preceding list (Section 2). Bristol University: Higher School Certificate Examination; Schools Certificate Examination. Cambridge Local Examinations and Lectures Syndicate: Higher School Certificate Examination; School Certificate Examination. Central Welsh Examination Board: Senior Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: General School Examination; Higher School Certificate Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations: Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

5. The Council will continue to recognise examinations conducted by educational bodies other than those (referred to in Section 4) directly recognised by the Universities of Great Britain. Recognition will not be extended under this section to any examination unless the Council is satisfied (1) that in scope and standard it is equivalent to a recognised Matriculation Examination of a British University, and (2) that it fulfils the conditions specified by the Council (Section 3, Sub-section (2)). Such examinations are:—The College of Preceptors (England): Senior Certificate. The Educational Institute of Scotland: Preliminary Medical Certificate.

Examinations in Ireland.—6. Subject to the specified conditions (Section 3, Sub-section (2)), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, the Matriculation Examinations of the National University of Ireland and the Queen's University of Belfast, the Preliminary Examination of the Irish Royal Colleges of Physicians and Surgeons, and the Senior Grade Intermediate Certificate of the Ministry of Education, Belfast, and all examinations accepted by one or more of these bodies as equivalent for purposes of entrance or Matriculation, to the above-named examinations.

7. The Council will recognise the Final Examinations for Degrees in Arts and Science of any University of the United Kingdom or of the British Dominions.

Colonial Examinations.—8. Subject to the specified conditions (Section 3, Sub-section (2)), the Council will recognise all examinations of Colonial Universities which are accepted by one or more of the British Universities as equivalent, for purposes of Matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

The registration of medical students is placed under the charge of the Branch Registrars.

A copy of the Medical Students Register prepared by each of the Branch Registrars is transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who supplies an alphabetical list of all students registered in the preceding year to each of the licensing bodies in the United Kingdom, and to each of the several medical schools and hospitals.

All applications for special exceptions to the foregoing regulations as to registration should be addressed to the Registrar of the General Council.

Lists of Universities (including their Colleges and Medical Schools) and Schools of Medicine at which Medical Study may be Commenced in the United Kingdom.—1. Universities (including their colleges): Aberdeen University; Belfast, Queen's University; Birmingham University; Bristol University; Cambridge University; Dublin University (including Trinity College); Durham University (including the Durham College of Medicine); Edinburgh University; Glasgow University (including Queen Margaret College); Ireland, National University (including University College, Cork; University College, Dublin; University College, Galway); Leeds University; Liverpool University; London University (including the following Schools and Colleges: St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College, King's College Hospital, London Hospital, St. Mary's Hospital, Middlesex Hospital, St. Thomas's Hospital, University College, Westminster Hospital, London (Royal Free Hospital) School of Medicine for Women; Bedford College, Royal Holloway College); Manchester, Victoria University; Oxford University; St. Andrews University (including University College, Dundee); Sheffield University; Wales, University of (including University College of Wales, Aberystwyth; University College of North Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; Welsh National School of Medicine, Cardiff; University College, Swansea). 2. Schools of Medicine Recognised by the Licensing Bodies:—Dublin: Royal College of Surgeons, Schools of Surgery; Edinburgh: School of Medicine of the Royal Colleges; Glasgow: Anderson's College, St. Mungo's College.

The address of the Registrar, to whom further communications should be addressed, is as follows: The Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1.

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

A Guide to the Facilities for Obtaining the Various Medical Degrees and Other Qualifications for the British Medical Register.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.[1]

This University confers two degrees in Medicine, those of *B.M.* and *D.M.*, two in Surgery, *B.Ch.* and *M.Ch.*, and diplomas in *Public Health and Ophthalmology*.

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. To obtain the degrees of B.M. and B.Ch. the following examinations must be passed: 1. Preliminary subjects: Physics and Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Honour School of Natural Science; Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Honour School of Natural Science: Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The first B.M. examination may be passed at any time after the Preliminary Scientific examinations. Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately.

At any time after passing the First Examination, the candidate can, on producing certificates, present himself for examination in the subjects of Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology; but cannot enter for examination in Medicine, Surgery and Midwifery until the eighteenth term from his matriculation, nor until a period of at least thirty-three months has elapsed from the date of passing the First B.M. Examination. He must pass in Medicine, Surgery and Midwifery at one and the same time.

Before admission to the Second B.M. Examination, the student must produce certificates of having attended laboratory courses in Pathology, Bacteriology and Pharmacology either in Oxford or in a recognised medical school. He must also produce certificates of having acted as Clinical Clerk and Dresser, each for six months, in a medical school approved by the University, of three months post-mortem clerking, of attendance on Labours, of instruction in Infectious Diseases and Ophthalmology, and of proficiency in vaccination and the administration of anæsthetics.

The degree of B.Ch. is granted with that of B.M. after passing the above examinations. The degree of D.M. is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by the examiners for the B.M. degree whose subjects are dealt with therein and by Professors in the Faculty of Medicine. The degree of M.Ch. is granted after examinations to Bachelors of Surgery in the University who have entered upon their twenty-first term, and who are Members of the Surgical Staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

The examinations for the Diploma in Public Health[2] in two parts are held in Trinity and Michaelmas terms; that for the Diploma in Ophthalmology is held annually, commencing on the third Monday in July.

For the Diploma of Ophthalmology attendance at a course of instruction in Oxford, lasting two months, and at approved courses of instruction in Clinical Ophthalmology during twelve months, is obligatory. Candidates must be registered medical men, unless, being Bachelors or Doctors of Medicine of Universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects. Animal Physiology, Botany, Zoology. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years; the exhibitions vary in value from £30 to £90 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

In addition to the University Lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the B.A. degree.

In the Radcliffe Infirmary and County Hospital elementary clinical instruction is given by the Regius Professor of Medicine, the Litchfield Lecturers in Medicine and Surgery, and the other physicians and surgeons. Instruction is also given in post-mortem work and Clinical Pathology in connexion with the courses in Pathology. Post-graduate courses are held at the beginning of October.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1923 (both of which are published by the Clarendon Press); from the Regius Professor of Medicine; from the Professors in the several departments of medical science; and from the Dean of the School of Medicine, Department of Medicine, Museum, Oxford.

---

[2] The regulations for the Diplomas in Public Health of the various Examining Bodies will be found on page 472.

University of Oxford: Radcliffe Infirmary and County Hospital.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. The hospital contains 210 beds. In connexion with the hospital there is usually held in each year during October a post-graduate course, lasting a week.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being a graduate of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing two Special Examinations for the ordinary B.A. degree, or an Honours degree in one of the Triposes. The Natural Sciences Tripos is taken most frequently, as some of the subjects are practically the same as those for the first and second M.B.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for M.B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) General and Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *second* is divided into three parts—viz., (1) Organic Chemistry, (2) Human Anatomy and Physiology; and (3) Pharmacology and General Pathology. The *third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic.

Candidates who have passed both parts of the third M.B. examination are admitted to the registrable degree of *Bachelor of Surgery* (*B.Chir.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A., to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery* (*M.Chir.*) the candidate must have passed all the examinations for B.Chir., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Chir.

Diplomas are granted in Public Health, in Hygiene, in Tropical Medicine, in Medical Radiology and Electrology, and in Psychological Medicine. Candidates must hold a recognised medical qualification.

Women Students.—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the First and Second M.B. Examinations under certain conditions.

University Prize in Medicine.—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, The Registry, Cambridge.

Diploma in Medical Radiology and Electrology.—This Diploma is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The Diploma is only open to those who hold a medical qualification, and includes a course of lectures and practical work in physics (Part I.), and in Radiology and Electrology (Part II.). Attendances at the necessary course of lectures in both subjects and in addition six months' clinical experience in an adequately equipped hospital recognised by the Committee is essential. The whole course of study takes six months, the lectures, practical work, and hospital attendance running concurrently. The Courses carried out by the University of Cambridge are at present arranged to begin early in January. Three months are spent in Cambridge doing the lectures and practical work in Part I., attending the systematic lectures in Part II., and the practice of Addenbrooke's Hospital, where there is a fully equipped and up-to-date X ray and Electrological Department. The remaining three months can be completed at any recognised hospital, but special arrangements are made for students to continue their studies in London, where demonstrations at various hospitals are arranged in order to give a wide experience. In addition, an independent course is arranged by the British Association of Radiology and Physio-Therapy. This Course is held entirely in London, but is recognised by the University as qualifying for the examination, and begins early in

October. Further particulars as to the Cambridge Course can be obtained from Dr. F. Shillington Scales, Medical Schools, Cambridge, and of the London Courses from Dr. Stanley Melville, at the Offices of the B.A.R.P., 12, Stratford Place, London, W. 1.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament, 1898, and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Lecturers were also appointed in special subjects.

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers —i.e., such as are appointed by the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby: or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*): the two higher degrees being open only to candidates holding the M.B., B.S. degrees of the University.

The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W. 7.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) *Attended* prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Tuesday following the third Monday in March and on the second Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital; (14) The conduct of at least 20 Labours; (15) Ante-natal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work; (17) General

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. The hospital contains 210 beds. In connexion with the hospital there is usually held in each year during October a post-graduate course, lasting a week.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being a graduate of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing two Special Examinations for the ordinary B.A. degree, or an Honours degree in one of the Triposes. The Natural Sciences Tripos is taken most frequently, as some of the subjects are practically the same as those for the first and second M.B.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for M.B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) General Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *second* is divided into three parts—viz., (1) Organic Chemistry, (2) Human Anatomy and Physiology; and (3) Pharmacology and General Pathology. The *third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic.

Candidates who have passed both parts of the third M.B. examination are admitted to the registrable degree of *Bachelor of Surgery* (*B.Chir.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A., to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery* (*M.Chir.*) the candidate must have passed all the examinations for B.Chir., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Chir.

Diplomas are granted in Public Health, in Hygiene, in Tropical Medicine, in Medical Radiology and Electrology, and in Psychological Medicine. Candidates must hold a recognised medical qualification.

Women Students.—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the First and Second M.B. Examinations under certain conditions.

University Prize in Medicine.—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, The Registry, Cambridge.

Diploma in Medical Radiology and Electrology.—This Diploma is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The Diploma is only open to those who hold a medical qualification, and includes a course of lectures and practical work in physics (Part I.), and in Radiology and Electrology (Part II.). Attendances at the necessary course of lectures in both subjects and in addition six months' clinical experience in an adequately equipped hospital recognised by the Committee is essential. The whole course of study takes six months, the lectures, practical work, and hospital attendance running concurrently. The Courses carried out by the University of Cambridge are at present arranged to begin early in January. Three months are spent in Cambridge doing the lectures and practical work in Part I., attending the systematic lectures in Part II., and the practice of Addenbrooke's Hospital, where there is a fully equipped and up-to-date X ray and Electrological Department. The remaining three months can be completed at any recognised hospital, but special arrangements are made for students to continue their studies in London, where demonstrations at various hospitals are arranged in order to give a wide experience. In addition, an independent course is arranged by the British Association of Radiology and Physio-Therapy. This Course is held entirely in London, but is recognised by the University as qualifying for the examination, and begins early in

October. Further particulars as to the Cambridge Course can be obtained from Dr. F. Shillington Scales, Medical Schools, Cambridge, and of the London Courses from Dr. Stanley Melville, at the Offices of the B.A.R.P., 12, Stratford Place, London, W. 1.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament, 1898, and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Lecturers were also appointed in special subjects.

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby: or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*): the two higher degrees being open only to candidates holding the M.B., B.S. degrees of the University.

The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W. 7.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) *Attended* prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine. Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Tuesday following the third Monday in March and on the second Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology: (13) Lying-in Hospital; (14) The conduct of at least 20 Labours (15) Ante-natal Clinic; (16) Experience as Clinical Clerk in Gynæcological Work; (17) Gen-

Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology and Rhinology. A thesis may be submitted as for M.D.

Fees.—Matriculation £2 12*s.* 6*d.* for each entry. at provincial examinations an additional local fee is charged. First examination for Medical Degrees: £6 6*s.* for each entry to the entire examination. For re-examination in one subject the fee is £2 2*s.* Second examination, Part I. £3 3*s.*, repeated on each subsequent entry; Part II. £9 9*s.* for the whole examination. Third examination: £12 12*s.* for each entry to the whole examination. M.D. Examination: £21; for re-examination £10 10*s.* M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Principal Officer, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. It receives over 9000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day, except Saturdays, at 1.30 P.M., and Surgical consultations are held on Thursdays at the same hour. Medical consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical lectures on all special subjects are also given. Wholetime Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board, and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

New Buildings.—The new buildings comprise residential quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the Medical College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, pathological histology, and pathological chemistry. *The Medical School Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. *Laboratory Instruction for the D.P.H.* is provided during the winter and summer sessions. Facilities for research work are afforded in the Clinical Units and the Laboratories of the pathological and other departments. *A Vacation Post-graduate Course*, adapted to the needs of general practitioners, is given annually. The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Scholarships given in aid of Medical Study.—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100; (*c*) Entrance Scholarship in Arts, £100; (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, and Anatomy; (*c*) and (*d*) are awarded after examination in Latin, Mathematics, and Greek or French or German; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The more important of the other Scholarships and prizes are as follows:—Four Junior Scholarships—(*f*) No. 1, £30, Anatomy and Physiology; (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3, £25, Chemistry, Physics, and Biology; (*i*) No. 4, £15, Chemistry, Physics, and Biology: (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (*n*) Sir G. Burrows Prize, 10 guineas, Pathology; (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105; (*r*) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115; and (*s*) Baly Scholarship in Clinical Medicine, £75, awarded by examination.

---

[1] For Ancillary Metropolitan Medical Schools see p. 435.

Information may be obtained on application to the Dean to the Medical College: Dr. T. W. Shore. The Warden of the Residential College is Mr. R. M. Vick.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Examination and Treatment.

Appointments.—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year after competitive examination.

Primary and Intermediate Studies.—By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk.

Final Studies.—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica, Toxicology, and Operative Surgery.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School. Students receive their training in Preventive Medicine, Pathology, and Bacteriology here, and are encouraged to undertake Research. Special facilities are available for Postgraduate Research and Study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital adjoining. Special lectures and demonstrations are arranged for Postgraduates.

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, "The Cuthbert Lockyer Collection."

Students' Club.—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c. The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society. An athletic ground, comprising six acres, has recently been acquired and is now in use.

Women Students.—Women students are admitted to the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments.

Fees.—Entrance: Primary and Intermediate, 10 guineas; Final, 8 guineas; Annual, £42.

Further information may be obtained on application to the Dean, Dr. W. J. Fenton, Medical School, Charing Cross Hospital, London, W.C.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 430 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for Diseases Peculiar to Women, and a Maternity Ward of 11 beds has been instituted recently. Children's beds are placed in the women's wards. Two wards are allotted to ophthalmic cases.

Entrance Scholarships and Endowed Prizes of a total value of £700 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at that College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Eight house physicians and eight house surgeons are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the posts (2) of Junior Anæsthetists, each at £30. The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Scholarships and Prizes.—At this school three entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two University Entrance Scholarships, 90 guineas and £70 respectively; (*c*) Devitt-Pendlebury Scholarship, £50, Anatomy and Physiology. This year, in addition to these Scholarships, Exhibitions, each of the value of £40 and up to eight in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*d*) William Brown Exhibition, tenable for two years and open to perpetual pupils having registrable qualifications, £150 per annum, Practice of Medicine, Midwifery, and Surgery; (*e*) William Brown Exhibition, tenable for three years and open to perpetual pupils qualified not more than three years previously, £49 per annum, Essay and Original Work; (*f*) Allingham Scholarship in Surgery for Students qualified not more than three years, £85; (*g*) and (*h*) two Brackenbury Prizes, *one* in Medicine *and one* in Surgery, £33 each. open to students of not more than five years' standing; (*i*) H. C. Johnson Memorial Prize, £19, Practical Anatomy; (*j*) Pollock Prize, £23, Physiology. Physiological Chemistry, and Histology; (*k*) Clarke Prize, £5; (*l*) Thompson Medal, £9, Clinical Reports; (*m*) Brodie Prize, £8, Clinical Reports; (*n*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*o*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications.

Further information may be obtained from the Dean of the Medical School, Dr. J. A. Torrens.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1724 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 626 beds. The whole of the *medical school* has been rebuilt during the last 27 years. It provides ample accommodation, with modern equipment, for all the non-clinical subjects of the medical curriculum. Within the grounds of the hospital are situated the residential college, with accommodation for 35 students. the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

House physicians, house surgeons, out-patien officers and assistant house surgeons, obstetri residents, house surgeons in the departments o

Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology and Rhinology. A thesis may be submitted as for M.D.

Fees.—Matriculation £2 12*s.* 6*d.* for each entry. at provincial examinations an additional local fee is charged. First examination for Medical Degrees: £6 6*s.* for each entry to the entire examination. For re-examination in one subject the fee is £2 2*s.* Second examination, Part I. £3 3*s.*, repeated on each subsequent entry; Part II. £9 9*s.* for the whole examination. Third examination: £12 12*s.* for each entry to the whole examination. M.D. Examination: £21; for re-examination £10 10*s.* M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Principal Officer, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. It receives over 9000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day, except Saturdays, at 1.30 P.M., and Surgical consultations are held on Thursdays at the same hour. Medical consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical lectures on all special subjects are also given. Wholetime Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board, and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

New Buildings.—The new buildings comprise residential quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the Medical College as well as a laboratory devoted to instruction in Public Health. ---

[1] For Ancillary Metropolitan Medical Schools see p. 435.

ment. Arrangements have been made for the use of this section, together with additional rooms for Dental Metallurgy, by the Dental School, which was opened in November last under the direction of Mr. A. Livingston, M.B., Ch.B., Mast. Dent. Surg. A full course is given in coöperation with King's College, and includes arrangements for students who desire to avail themselves of the special provisions of the Dentists Act.

Athletics.—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. An athletic ground, over six acres in extent, has been provided for the use of the students on Dog Kennel Hill, about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Platanes"—a hall of residence available for students belonging to the hospital.

Fees.—The composition fee for Hospital work and Final Medical subjects of the curriculum is 93 guineas if paid in one sum, or 95 guineas if paid in two instalments, in addition to the Entrance Fee of 10 guineas. The Calendar of the School will be sent on application to either of the following: Dr. H. Willoughby Lyle, *Dean;* Mr. S. C. Ranner, *Secretary of the Medical School*, King's College Hospital, Denmark Hill, S.E. 5.

London Hospital.—The hospital, with its Medical College and Dental School, is situated in the Mile End-road, E. The hospital contains 948 beds, which are in constant use, and is the only general hospital for East London. During last year 17,977 in-patients and 119,749 out-patients received treatment, while 7543 major operations were performed. 39,092 out-patients attended the special departments for diseases of the Eye, Ear, Nose and Throat, Skin, Teeth, &c., and the Pediatric, Orthopædic, Venereal, Radiological, Electro- and Physico-Therapeutical and Inoculation Departments. The hospital presents, therefore, a large field for clinical instruction, and in its Wards and Out-patient Departments exceptional opportunities are afforded for acquiring an extensive and practical experience in all phases of disease.

A Clinical Unit in Medicine, under the charge of a whole-time director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and coördination of medical research.

To each medical and surgical firm throughout the hospital there is attached a First Assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. Special courses of lectures and demonstrations are arranged in Medicine and Surgery and their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital. Holders of resident appointments have free board. Special classes are held for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, for the Membership of the Royal College of Physicians, and for other higher examinations. Special entries for medical and surgical practice can be made. A residential Hostel on hospital grounds is provided for the convenience of students. The Clubs Union Athletic Ground of over 13 acres is within easy reach of the hospital.

Scholarships and Prizes.—The following is a list of the Scholarships and Prizes:—Price Scholarship £100, and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarship, open to students of Oxford and Cambridge Universities, £75, Human Anatomy and Physiology; Buxton Prize, £10, subjects of Anatomy and Physiology; three Prizes for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynæcology; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine, and Surgery; Letheby Prizes (2), £25, Chemistry and Chemical Pathology; eight Dressers' Prizes, amounting to £40, zeal, efficiency, and knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £60, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology; James Anderson Prizes (4), £20, Elementary Clinical Medicine; Arnold Thompson Prize, £15, Diseases of Children; and Liddle Prize, triennial, £120.

Medical Research Funds.—Research Funds of over £26,000, including the Eliza Ann Alston Endowment Fund for Medical Research, provide valuable scholarships for men wishing to undertake research or desirous of preparing Theses for University degrees.

Dean: Professor William Wright, London Hospital Medical College, E. 1.

St. Mary's Hospital Medical School.—The Hospital and Medical School are situated close to Paddington station (G.W.R.) having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 305 beds and, by a scheme of affiliation, for teaching purposes, of certain neighbouring hospitals, the teaching facilities extend over 1000 beds. The Athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains. A large pavilion has recently been added.

Clinical Facilities.—Clinical Units in Medicine and Surgery were established in 1920, and have now been formally recognised by the University Grants Committee, St. Mary's being one of the six Medical Schools in London which enjoy this privilege. Lying-in beds have recently been added, and, in addition to this, arrangements have been made by which all students take out a short course of instruction in Practical Midwifery at Queen Charlotte's Hospital without additional fee.

Institute of Pathology and Research.—Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S.

Appointments.—Research Scholarships of £200 each are awarded annually to students working in the departments of the institute; and preparation is being made to open 13 research beds. Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually.

Complete Curriculum.—The Medical School provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Entrance Scholarships.—Three Entrance Scholarships of the value of £210 each are awarded annually. Two University Scholarships of £200 each are awarded annually.

Fees.—Composition Fee for entire curriculum (5½ years) £200 in one sum, or £210 by four annual instalments. Composition Fee for Clinical curriculum (2½ years) 90 guineas in one sum, or 95 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas.

Middlesex Hospital.—The hospital contains over 450 beds, with special wards for Cancer, Maternity and Gynæcological and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and ophthalmology and genito-urinary diseases, house physician, department for diseases of children, clinical assistants, clerks to anæsthetists, surgeons' dressers, medical clinical clerks, post-mortem clerks, extern obstetric dressers, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit. There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

The following special departments are attached to the hospital: Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actino-therapeutics, anæsthetics, dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children).

Scholarships. — Six entrance scholarships are awarded annually as follows:—(*a*) one War Memorial scholarship, providing a free Medical Education for five years of the value of £200, to be awarded alternately in Arts and Science (next award, July, 1924); (*b*) one Arts scholarship of £100 for students under 21 years of age, Latin, English, Greek, or French or German, Arithmetic, Euclid, and Algebra; (*c*) one Science scholarship for students under 21 years, £100; subjects, any two of the following: Inorganic Chemistry, Physics, and Biology; (*d*) a Junior Science scholarship of the value of £100 is offered for competition, annually in July, to candidates who have attended Preliminary Science Classes at this School; (*e*) two open Science scholarships: (1) a War Memorial scholarship of the value of £80, awarded annually in September; (2) an open scholarship of the value of £80, awarded annually in September, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School; subjects, any two of the following: Anatomy, Physiology, Organic Chemistry, Pharmacology, General Pathology.

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates, the term "military service" meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the war; or (2) in respect of other approved duties in connexion with national defence.

The Dean of the Medical School is Professor T. B. Johnston, from whom further information may be obtained.

UNIVERSITY OF LONDON: KING'S COLLEGE.—The medical department (Faculty of Medical Science) at this College only deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants to students entering the College directly and also to students of the following four hospital schools which prepare only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital. The department is open to both men and women.

Scholarships.—(*a*) Two Warneford Entrance Scholarships of £30 each for four years. Examination in July, subjects selected from Divinity, Classics, Science. (*b*) Sambrooke Scholarship of £30 for three years. Examination in April or May, subjects selected from Classics, Science. (*c*) Worsley Scholarships: £100 in five annual instalments of £20. (*d*) Rabbeth Scholarship of £20 for best work in first year. (*e*) Second Year Scholarship of £20 tenable for one year. (*f*) Daniell Scholarship of £40 for one year. Awarded on results of University Honours Examination.

Fees.—Tuition fee of 35 guineas for the first year, £42 per annum for the second and third years, with a materials fee of 4 guineas in the first year, 6 guineas in the second year, 4 guineas in the third year. For prospectus and further information application should be made to the Dean of the Medical Faculty (Professor E. Barclay-Smith), King's College, Strand, W.C. 2.

Dental Course.—The College, in association with King's College Hospital, has instituted courses for the Degree in Dental Surgery of the University of London and for the Dental Diploma of the Conjoint Board.

Fees.—First year (Chemistry and Physics), 20 guineas; second and third years (Anatomy, Physiology, Dental Mechanics, and Dental Metallurgy), 52 guineas per annum. Fourth and fifth years (Hospital), 60 guineas per annum. For prospectus and further information application should be made to the Secretary, King's College Hospital Medical School, Denmark Hill, S.E.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The advanced subjects in the curriculum are taught at the Medical School attached to King's College Hospital, which is situated at Denmark Hill, S.E. 5. The hospital stands in the midst of a South London population, from which an immense amount of clinical material is forthcoming. During the past year there were 208,955 attendances in the out-patient and casualty departments. Accommodation for 400 beds for in-patients has been built, and provision will ultimately be made for 600 beds. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physicotherapy, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry. The appointments open to students are those of clinical assistant to the special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers, house physicians and house surgeons; resident anæsthetist; resident radiologist; bacteriologist; clinical pathologist; pathological registrar; and medical, surgical, and obstetric registrarships. Fifteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Prizes.—(*a*) Warneford Scholarships, (*b*) Sambrooke Scholarship, (*c*) Rabbeth Scholarship, £20 (see above); (*d*) Medical Entrance Scholarships, £50 (Anatomy and Physiology), and £50 (Pathology and Pharmacology) open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (*e*) A Medical Entrance Scholarship in Science, value £50, tenable for five years, successful candidates to study at King's College and King's College Hospital; (*f*) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (*g*) Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital; (*h*) Carter Prize, £15, Botany; (*i*) Tanner Prize, £10, Obstetrics and Diseases of Women; (*j*) Todd Prize, £4 4*s.* and medal, Clinical Medicine; (*k*) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the nomination of the Regius Professors; (*l*) an Epsom College Scholarship, value £50, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London. The Warneford and Sambrooke Scholars are required to take the subjects of the preliminary and Intermediate examinations at King's College, and the final subjects at King's College Hospital.

Dental School.—When the Hospital was built accommodation was provided for a Dental Depart- accommodation was provided for a Dental Depart-

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first year of study; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in any two of the following subjects: Anatomy, Physiology, and Chemistry. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Cheselden Medal, Surgery and Anatomy; (*e*) Mead Medal, Medicine, Pathology, and Hygiene; (*f*) Toller Prize, Medicine, Pathology, and Hygiene; (*g*) Bristowe Medal, Pathology, and Morbid Anatomy; (*h*) Solly Medal and Prize, biennially, Surgical Reports; (*i*) Clutton Memorial Medal in Clinical Surgery, biennial; (*j*) Wainwright Prize, Medicine, Pathology, and Hygiene; (*k*) Hadden Prize, Pathology; (*l*) Beaney Scholarship, £50 biennially, Surgery and Surgical Pathology; (*m*) Sutton Sams Prize, biennially, reports of cases in Obstetric Medicine; (*n*) Grainger Testimonial Prize, £31 10*s*., Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology.

The Dean of the Medical School is Sir Cuthbert S. Wallace, and the Medical Secretary Dr. A. Elliot, from whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics. Chemistry, Botany, and Zoology (the Preliminary Medical Sciences; also the Departments of Anatomy, Histology, Physiology, Biochemistry, and Pharmacology (the Intermediate Medical Sciences), and the Department of Hygiene and Public Health. Research work is undertaken in all departments. The completion of the Institute of Medical Sciences, which the generosity of the Rockefeller Foundation made possible, provides exceptional facilities for research and post-graduate study in anatomy, physiology, and pharmacology. In particular might be specified the opportunities for investigation in human and comparative embryology and neurology, in histology, radiology, anthropology, biochemistry, and experimental physiology and experimental embryology. Arrangements have also been made for the closer correlation of work in the Institute with that of University College Hospital and its Medical School.

Faculty of Medical Sciences.—Composition Fees.—For the courses required by the University of London. 1. For the First Medical Course, 35 guineas, entitling to one attendance and to the privileges of the Union Society for one session. 2. For the Second Medical (Intermediate) Course 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance at Anatomy and Physiology during three years and to one attendance at Organic and Applied Chemistry, and Pharmacology, and to the privileges of the Union Society or the Women's Union Society for two sessions.

For the medical education required by the Examining Board in England: (i) For the course for the Premedical Examination, 35 guineas, entitling to attendance and to the privileges of the Union Society for one session. (ii) For the course for the First Examination, 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance during three years (including one attendance at each Practical Course in Physiology) in all subjects except Practical Pharmacy. It also entitles to the privileges of the Union Society for two sessions.

Scholarships and Prizes.—The first three items on the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (*a*) The Bucknill Scholarship, 135 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (*d*) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, and Chemistry; (*e*) Schafer Prize in Physiology, £18 triennially; (*f*) Sharpey Physiological Scholarship, £105, Biological Sciences; (*g*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £16 a year; and (*h*) five Gold and five Silver Medals awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Dean: Sir George Blacker. Vice-Dean: Mr. Gwynne Williams. Secretary: Mr. G. E. Adams. Open to men and a limited number of women students. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B.S. (London) Course, 112 guineas if paid in one sum, 115 guineas if paid in two instalments, as follows—first year, 70 guineas; second year, 45 guineas. This fee entitles to attendance on lectures and hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, Durham, and other British Universities, and for the medical education required by the Examining Board in England and the Society of Apothecaries. There are over 300 beds in the hospital.

Clinical Units in Medicine and Surgery are now in operation. The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Out-patient Department of the hospital. A Unit in Obstetric Medicine will be established as soon as the new Obstetric Hospital now in course of construction is finished.

The new buildings of the Obstetric Hospital of 60 beds (rendered possible by the Rockefeller Benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension to the Nurses' Home, and the new research laboratories for the Medical School, are well under way, and these buildings should be ready for occupation by the spring of 1925.

Special Departments, Clinical and Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments tenable by Students.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Twelve house physicians, eight house surgeons, four senior and four junior obstetric assistants (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: Resident Medical Officer, Surgical Registrar, Obstetric Registrar, Harker-Smith Cancer Registrar, Casualty

Throat, and Skin; Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electro-Therapeutic department. The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electro-Therapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

The Medical School, which now includes the Bland-Sutton Institute of Pathology and the Cancer Research Laboratories is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly, commencing in April and October. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 Professors, 29 recognised Teachers, 8 Demonstrators, 4 tutors. The Bland-Sutton Institute of Pathology is completely equipped for routine hospital investigations, teaching and research work, and contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility for study.

Other features of interest are: the institution of a course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone. Primary F.R.C.S. class will resume in July.

Special classes are held to prepare students for the Intermediate Examinations of the Universities.

Hospital Appointments.—All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anæsthetist, and two resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. Eight registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

Scholarships, Prizes, &c.—(*a*), (*b*). Two Entrance Scholarships, value £100 each, and (*c*) a University Scholarship, value £50, are awarded annually in September. The successful candidates are required to become general students of the school. (*d*) A Freer Lucas Scholarship for Foundationers or Council Exhibitioners of Epsom College is awarded annually on the nomination of the Headmaster. There are also, (*e*) and (*f*), two Broderip Scholarships, value £60 and £40 respectively; (*g*) the Lyell Gold Medal and Scholarship, value £55 5*s.*; (*h*) the John Murray Medal and Scholarship, value £25 (awarded every third year); (*i*) the Freeman Scholarship, value £30; (*k*) the Hetley Clinical Prize, value £25; (*l*) the Leopold Hudson Prize, value 11 guineas; and (*m*) the Second Year's Exhibition, value 10 guineas. There are also numerous class prize examinations.

Fees.—The fees are arranged on a basis of an annual payment of approximately £42 for the six years of the curriculum. After six years, if the student is not qualified, the annual fee is £21.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, Musical Society, the cricket club, the football clubs, the athletic club, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. There are a restaurant and gymnasium in the school buildings, and large athletic grounds at Wembley, with new pavilion. A subscription to the Amalgamated Students' Club is payable by all General and Dental students. Full particulars on application to the Dean, Middlesex Hospital Medical School, W. 1.

St. Thomas's Hospital.—This Hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 644 beds. The in-patients last year numbered 9930, whilst the number of attendances as out-patients, including the casualty and light departments, was 462,287. There are special departments for the treatment of women, children, the eye, ear, nose and throat, skin, teeth, and for orthopædics. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for light treatment, X rays, and the Physico-therapeutics are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day, except Saturdays, at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. All appointments in the hospital are open to students without extra fee. Appointments open to students before qualification: Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists. The Students' Club comprises a spacious restaurant and smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments Open to Students after Qualification.—A Resident Assistant Physician, a Resident Assistant Surgeon, and a Resident Anæsthetist are appointed annually at a salary of £200 each per annum. Two Hospital Registrars, Medical and Surgical, at an annual salary of £250 each are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An Obstetric Tutor and Registrar, an Ophthalmic Registrar (at an annual salary of £50 each), and an Orthopædic Registrar (unpaid) are appointed yearly. Two Senior Resident Casualty Officers (Medical and Surgical) are appointed yearly. Eight Resident Casualty Officers and Anæsthetists are appointed every six months. Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months. Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for re-election. There are three Assistants in the Department of Pathology; the Senior receives £600 a year, and the two Juniors £450 each.

Fees.—The annual fees are: For each year of study £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, 5, Mecklenburgh-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies.

Scholarships and Prizes.—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years and next to be awarded in 1925. (*d*) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1927, £90. (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1926, £14 10*s*. (*i*) John Byron Bursary, tenable for two years, for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st, £20. (*k*) Helen Prideaux Prize, awarded every second year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £40. (*l*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1925. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s*. a year, awarded in alternate years; next award in July, 1925. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1928. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2*s*. and £1 1*s*. are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5*s*., is awarded yearly. The Edith Pechey Phipson Prize in Pharmacology, value £3 3*s*., is awarded annually.

The Dean of the Medical School is Miss Aldrich-Blake, M.D., M.S.; the Honorary Secretary, Dr. May Thorne; and the Warden and Secretary, Miss L. M. Brooks, to whom inquiries may be addressed.

UNIVERSITY OF DURHAM.

To return to the curriculums of the Universities, there are six English provincial universities providing a full course for the medical student.

Two Diplomas, one Licence, and nine degrees are conferred—viz., the Diploma in Public Health, Diploma in Psychiatry, the Licence in Dental Surgery, and the degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, Doctor of Hygiene, Bachelor of Dental Surgery, and Master of Dental Surgery.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Biology and Organic Chemistry. The subjects of the Second Examination are—Anatomy and Physiology. The subjects for the Third Examination are—Materia Medica and Pharmacy, Pharmacology, Medical Jurisprudence, Public Health, and Pathology and Elementary Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine, Surgery and Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Therapeutics, Psychological Medicine, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children, and Ophthalmology. It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special examination in the Theory and Practice of Medicine. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Doctor of Surgery.—The University of Durham grants the Degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, and not less than 24 years of age. They must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery and ancillary subjects. One at least of the three years must be spent in the University. The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology and Bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad. The fee for the examination is £20, and the fee for the degree is £10.

Candidates for any of the above degrees, diplomas, or licence, must give at least 28 days' notice to Professor Howden, Registrar, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before the 1st of April.

Scholarships and Prizes.—In connexion with this University the following Scholarships and prizes are awarded:—University of Durham Entrance Scholarship, £25 a year for four years; Pears' Entrance Scholarship, £10 a year for three years (awarded every third year); Province of Durham Masonic (Entrance) Scholarship, £30; Heath Scholarship for Surgery, £200, available every second year.

The following Scholarships are tenable for one year, namely:—Tulloch Scholarship for Elementary Biology

Medical Officer and a Casualty Surgical Officer, Assistants in Ear and Throat, Ophthalmic, Skin and Venereal Diseases Departments, and House Anæsthetist.

Museum of Pathological Anatomy.—The Museum is open for study from 9 A.M. to 5 P.M. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 13,500 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the Medical School are required to become members. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London University College, is situated near the G.W.R. station at Perivale.

Scholarships and Prizes.—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions, 112 guineas each, Anatomy and Physiology; (*e*) Graham Scholarship in Pathology, £300 per annum for two years, awarded by the Senate of the University of London; (*f*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*g*) Atchison Scholarship, tenable for two years, £55 per annum, General Proficiency in Medical Studies; (*h*) Magrath Clinical Scholarship, about £100, Clinical Cases; (*i*) Percival Alleyn Scholarship, about £60, Surgery; (*j*) Filliter Exhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10*s*., Practical Surgery; (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*m*) two Liston Gold Medals for Clinical Surgery; (*n*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*o*) Tuke Silver and Bronze Medals for Pathology. (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology. (*q*) Leslie Pearce Gould Travelling Scholarship for Surgery.

Residence of Students.—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers.

WESTMINSTER HOSPITAL.—The hospital contains 236 beds and affords relief to upwards of 2500 in-patients and 25,000 out-patients annually. There are separate departments for Diseases of the Eye, Skin, Teeth, Ear, Nose, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, for Venereal Diseases, and for Massage, Electrical and Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments are open to male and female students.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £70 each. Summer Session: Two Scholarships in Anatomy and Physiology, £70 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Reports on Cases; Clinical Surgery Prize, £5, Reports on Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, tenable for two years, £20, Chemistry; Rabbeth Scholarship, open to First-year Students, £20; Class Examinations in the Preliminary Scientific Course; and the Sambrooke King's College Scholarship in Science, value £25. Inquiries and requests for Prospectus may be addressed to the Dean, Dr. A. S. Woodwark.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £240 in five instalments. This sum includes library and laboratory fees. Arrangements are made for pre-medical courses in Chemistry and Physics, which are included in these fees.

The Royal Free Hospital contains 240 beds. The Hospital also has large Casualty and Out-patient Departments, and Departments for Special Diseases. A new and specially equipped block contains the Obstetrical and Gynæcological Unit which, with the Marlborough Maternity Department, controls 68 beds. A Maternity District is attached to the Unit. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, South London Hospital, and Royal London Ophthalmic Hospital.

Courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the Royal London Dental Hospital, Leicester-square.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants, exceptional merit may exempt from any part of these examinations.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and to submit themselves for oral and possibly written examination.

Fees.—Matriculation, £2; First Examination, Part I., £2 10s.; First Examination, Part II., £2 10s.; Second Examination, £2 10s.; Third Examination, £2 10s.; Final Examination. £10; M.D. or Ch.M., £12 10s.

At the University of Birmingham the following Scholarships are awarded:—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland (will be offered in 1925); (*b*) two Ingleby Scholarships of £10 each awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 10 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*e*) Dental Scholarship of £37 10s., Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10s. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate passing the Final M.B., Ch.B. in June, who obtains the highest marks in Clinical Medicine, provided the marks so gained be not less than 60 per cent. The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in the fourth and fifth years (open to all students).

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board. The hospitals possess more than 600 beds, treating annually about 9000 in-patients and 70,000 out-patients. The curriculum is adapted in the first place to the University of Birmingham, but it also meets the requirements of the examinations of other licensing bodies. At the General Hospital there are open to the students the following appointments: A surgical registrar, £200 per annum; a resident medical officer, elected annually (£155); a resident surgical officer, elected annually and eligible for re-election for three years (£180); a resident pathologist, elected for six months (£100); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £70 a year; two house surgeons to the gynæcological, ophthalmic, and aural departments are elected every six months, receiving board, residence, and a salary of £70 a year; two assistant house surgeons are elected every three months, receiving board, residence, and salaries at the rate of £40 a year, and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £70 a year. One casualty house surgeon who holds office for three months at salary at rate of £70 a year. Four non-resident obstetric students who hold office for one month and receive board only on payment of one guinea per week. Thirty-eight other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Mental Hospitals, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopædic and Spinal Hospital, at the Maternity Hospital, and at the Ear and Throat Hospital.

Post-graduate Courses.—A Lectureship in Morbid Psychology was established in 1919 in the University. and courses of lectures are given annually by specialists in the subject. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers. Post-graduate Courses of Clinical Demonstrations (for General Practitioners) at the Birmingham General and Queen's Hospitals were held from April to August, 1924. Further courses will be arranged later.

Birmingham General Hospital.—370 beds are in daily use, 6000 in-patients per annum. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, Septic and Infectious cases; special beds for Eye and Skin cases. About 50,000 out-patients per annum. Laboratories for Bacteriology and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electro-therapy, Extern Midwifery, and Venereal Diseases. Post-graduate classes are held in every branch of medicine and surgery. The Jaffray Branch Hospital contains 56 beds.

Queen's Hospital (Beds 224).—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynæcology and ophthalmology, dentistry, radiography, pathology, bacteriology, massage, electricity, whirlpool baths, electro-cardiograph, &c.

Birmingham and Midland Eye Hospital, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of over 250. Students attending for a period and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology; Gold Medal and £20; Charlton Scholarship for Medicine, £25; Gibb Scholarship for Pathology, £28; Luke Armstrong Scholarship for Comparative Pathology, £25; Stephen Scott Scholarship for Surgery, £40; Philipson Scholarships for highest marks in Final M.B., B.S. Examinations, two of £48 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £325; Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy; and Outterson Wood Prize for psychological Medicine, £10. At the end of each session a Prize of Books is awarded in each of the regular classes. For further information apply to Professor R. Howden, Registrar of the College.

The College of Medicine, Newcastle-upon-Tyne.—Clinical instruction is given at the Royal Victoria Infirmary, containing about 550 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Post-graduate classes are held.

The Bacteriological Laboratory.—A new Bacteriological Laboratory has recently been erected adjacent to Armstrong College.

The Princess Mary Maternity Hospital.—The new Maternity Hospital, containing 65 beds, was opened by H.R.H. Princess Mary Viscountess Lascelles in November last. The hospital is thoroughly up to date, excellently equipped, and there is an annual indoor and outdoor attendance on 3000 cases.

Students' Union.—Students' Union Buildings are being erected at a cost of about £40,000 and will be opened early in 1925. Separate accommodation (non-residential) is provided for men and women students.

Newcastle-upon-Tyne Royal Victoria Infirmary.—The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII. in 1906. The number of beds is 550. The number of in-patients annually is 12,000 and out-patients' attendances 297,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians and Assistant Surgeons, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1924 opens on Oct. 1st and the summer session of 1925 on April 14th. Applications for detailed information should be made to the Dean, Dr. Horsley Drummond, at the hospital.

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Princess Mary Maternity Hospital, Newcastle-upon-Tyne, which contains 65 beds, with an annual indoor and outdoor attendance on 3000 cases. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is further taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye.

Post-Graduate Instruction.—For the year 1924–1925 the following post-graduate courses have been arranged:—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose and Ear; Diseases of the Skin; Venereal Diseases; Neurology. Special courses in Midwifery will be held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the early part of the Summer Vacation, 1925. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary for specified periods.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof, and a recognised Pre-Medical Examination in Chemistry and Physics. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Part I., Elementary Biology and Organic Chemistry.—Part II., Anatomy and Physiology. Second Examination.—General Pathology and Bacteriology, Materia Medica, and Practical Pharmacy. Third Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, Therapeutics, and Special Pathology. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital one month, and mental hospital three months. Vaccination instruction must be taken out and courses of Ophthalmology, Venereal Diseases, Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver, for the M.Ch. A thesis of exceptional merit may exempt from any part of these examinations.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and to submit themselves for oral and possibly written examination.

Fees.—Matriculation, £2; First Examination, Part I., £2 10s.; First Examination, Part II., £2 10s.; Second Examination, £2 10s.; Third Examination, £2 10s.; Final Examination, £10; M.D. or Ch.M., £12 10s.

At the University of Birmingham the following Scholarships are awarded:—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland (will be offered in 1925); (*b*) two Ingleby Scholarships of £10 each awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*e*) Dental Scholarship of £37 10s., Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10s. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate passing the Final M.B., Ch.B. in June, who obtains the highest marks in Clinical Medicine, provided the marks so gained be not less than 60 per cent. The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in the fourth and fifth years (open to all students).

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board. The hospitals possess more than 600 beds, treating annually about 9000 in-patients and 70,000 out-patients. The curriculum is adapted in the first place to the University of Birmingham, but it also meets the requirements of the examinations of other licensing bodies. At the General Hospital there are open to the students the following appointments: A surgical registrar, £200 per annum; a resident medical officer, elected annually (£155); a resident surgical officer, elected annually and eligible for re-election for three years (£180); a resident pathologist, elected for six months (£100); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £70 a year; two house surgeons to the gynæcological, ophthalmic, and aural departments are elected every six months, receiving board, residence, and a salary of £70 a year; two assistant house surgeons are elected every three months, receiving board, residence, and salaries at the rate of £40 a year, and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £70 a year. One casualty house surgeon who holds office for three months at salary at rate of £70 a year. Four non-resident obstetric students who hold office for one month and receive board only on payment of one guinea per week. Thirty-eight other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Mental Hospitals, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopædic and Spinal Hospital, at the Maternity Hospital, and at the Ear and Throat Hospital.

Post-graduate Courses.—A Lectureship in Morbid Psychology was established in 1919 in the University, and courses of lectures are given annually by specialists in the subject. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers. Post-graduate Courses of Clinical Demonstrations (for General Practitioners) at the Birmingham General and Queen's Hospitals were held from April to August, 1924. Further courses will be arranged later.

BIRMINGHAM GENERAL HOSPITAL.—370 beds are in daily use, 6000 in-patients per annum. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, Septic and Infectious cases; special beds for Eye and Skin cases. About 50,000 out-patients per annum. Laboratories for Bacteriology and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electro-therapy, Extern Midwifery, and Venereal Diseases. Post-graduate classes are held in every branch of medicine and surgery. The Jaffray Branch Hospital contains 56 beds.

QUEEN'S HOSPITAL (Beds 224).—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynæcology and ophthalmology, dentistry, radiography, pathology, bacteriology, massage, electricity, whirlpool baths, electro-cardiograph, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of over 250. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available on various subjects when a sufficient number of graduates are present. A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Doctor in Philosophy (Ph.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry; (2) Physics; (3) Biology (Zoology and Botany). The subjects of the Second Examination are (*a*) (1) Anatomy; (2) Physiology (including Physiological Chemistry and Histology); and (*b*) (3) Elementary Bacteriology, (4) Clinical Chemistry, (5) General Pathology. Candidates may present themselves in (*a*) or (*b*) separately. The subjects for the Final Examination are: (*a*) (1) Special Pathology and Morbid Anatomy; (2) Forensic Medicine and Toxicology; (3) Public Health; (4) Pharmacology and General Therapeutics; (*b*) (5) Obstetrics and Diseases of Women; (6) Surgery, Systematic, Clinical, Operative and Practical, including Ophthalmology; (7) Medicine, Systematic and Clinical, including Therapeutics, Mental Diseases, and Diseases of Children. Candidates may present themselves in Parts (*a*) and (*b*) separately, but candidates must have completed the fifth year of medical study before taking Part (*b*).

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least two years have elapsed since he passed the examinations for those degrees, or, in the case of the degree of Doctor, unless, having obtained substantially equivalent degrees in an approved University, he has subsequently spent two years in the University or in the Clinical School in the performance of research or the conduct of systematic clinical observations. Candidates for the degree of Doctor of Medicine are required to present a thesis together with, if desired, published original work relative to medical science. An examination is required if the work submitted is not of special merit. If the work submitted is of special merit, but extremely specialised, a candidate may be asked to submit a reasoned report on a subject set by the examiners.

The University has recently established a Diploma in Medical Radiology and Electrology—Part I., Physics; Part II., Radiology and Electrology. The parts may be taken at one examination or separately.

At this University the following Scholarships and Fellowships and Prizes are awarded:—(*a*) and (*b*) Robert Gee Entrance Scholarships, two annually, of £25 each tenable for two years Joint Matriculation Board Examination held in July, open to First M.B. Course Students; (*c*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects; (*d*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination among Senior Students in Anatomy, Physiology, Pharmacology, and Materia Medica; (*e*) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects, and Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students; (*f*) University Scholarship of £25 for one year, awarded on results of Second Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £150 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Bio-Chemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £150, for one year; (*m*) Ethel Boyce Fellowship in Gynæcological Pathology, of £100, for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; (*p*) Lady Jones Research Fellowship in Orthopædic Surgery, £200; (*q*) Samuels Memorial Scholarships, three at £20; numerous prizes and medals.

Medical School Buildings.—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. A new building for Tropical Medicine has recently been opened.

Clinical Instruction.—The Clinical School of the University consists of four general hospitals—the **Royal Infirmary**, the **David Lewis Northern Hospital**, the **Royal Southern Hospital**, and the **Stanley Hospital**; and of six special hospitals—the Eye and Ear Infirmary, the Hospital for Women, Liverpool Maternity Hospital and Ladies' Charity, the Royal Liverpool Children's Hospital, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1445 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine is awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations. (These are now under revision.)

The First Examination.—(1) Chemistry and Physics; (2) Biology. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Inorganic and Elementary Organic Chemistry and Physics; Part 2, Biology. The candidates sit for these parts separately.

The Second Examination.—(1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry.

The Third Examination.—(1) Pathology; (2) Pharmacology and Therapeutics.

The Final Examination.—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts.

Candidates for the Second Part of the Final Examination must have completed the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Scholarships, Fellowships, and Prizes.—At this University there are 22 Foundation Scholarships, 12 Exhibitions, five being for subjects connected with medical study, a Surgical Prize, a University Fellowship (Leech Fellowship, £100), Research Fellowships in Public Health, and Honorary Research Fellowships. 13 Entrance Scholarships are tenable for Medical courses; one Scholarship is offered in Surgery, Biology, Physiology, and Diseases of Children respectively, and one General Medical and Surgical. Exhibitions are offered in Physiology and Anatomy, and one for French and German. "The Dumville" Surgical Prize is awarded on the results of the Final Examination in Surgery in the Summer Term, £15. The Leech Fellowship (£100) is for the encouragement of study and research, and is open to persons who have graduated M.B., Ch.B., in the University not more than 18 months previously. The Honorary Research Fellowships, tenable for two years, conferring the right of free use of the laboratories, are awarded generally in October on application, with evidence of capacity for independent investigation.

There are many entrance scholarships, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Royal Infirmary Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Clinical Instruction.—THE MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 663 patients (including 54 beds at the Central Branch). The medical side consists of five units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing and apparatus rooms, and its own class-room attached. All of these units are occupied. In the educational block is a large lecture theatre and a museum. In the same building is housed the X ray department, which has nine separate X ray outfits for different purposes, and in which one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with this department.

The number of patients treated during the year 1923 was 12,705 in-patients, and 49,227 out-patients; of the latter figure 9144 were treated in the accident room of the Infirmary. About 9000 operations are performed annually in the operation theatres.

Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 132 beds; (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the City, which has now accommodation for 54 patients. The Associated Hospitals thus contain 1225 beds and are under the same management. Women students are admitted on the same terms as men.

Fees.—Medical Practice: Three months, 7½ guineas; six months, 12 guineas; twelve months, 18 guineas; full period required by the Examining Bodies, 60 guineas.

Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

The Dean of Clinical Instruction is Dr. T. H. Oliver.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and St. Anne's-on-the-Sea.—The hospital contains 190 beds and 28 in the Convalescent Home, St. Anne's-on-the-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electro-therapeutic Department. Two Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is a new Orthopædic Department. A special out-patients' day is held on Tuesday mornings at Gartside-street, and a ward at Pendlebury is devoted to cases needing operative treatment. Out-patients are seen daily at 9 A.M. at the Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 72 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Zoology and Botany. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Disease and Diseases of Children; Surgery—Systematic, Clinical, and Practical; Obstetrics, and Gynæcology—Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

These conditions are at present under review in connexion with the recommendations of the General Medical Council.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, may be required to pass an examination.

The first term commences on Oct. 1st. Prospectus, &c., can be obtained from the Academic Sub-Dean of the Medical School.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods may do so on terms which may be obtained from the Clinical Sub-Dean.

Clinical Instruction.—**THE LEEDS GENERAL INFIRMARY**, in connexion with this medical faculty, has accommodation for 632 in-patients, including 88 beds at branch hospitals in the country. During 1922 10,277 in-patients and 41,857 new out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

The First Examination.—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

The Second Examination.—The subjects of the examination are Anatomy and Physiology. Candidates must have completed the second year of professional study.

The Third Examination.—The subjects of the examination are Pathology, Pharmacology, Anatomy and Physiology. Candidates must have completed the Lent Term of the fourth year of professional study.

The Final Examination.—The subjects of the examination are:—Part I.—Forensic Medicine and Public Health; Part II.—Medicine (including Mental

Diseases and Diseases of Children). Surgery. Obstetrics (including Gynæcology). Candidates for Part I. must have completed the Michælmas Term of the fifth year of professional study: candidates for Part II. must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B, Ch.B. at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy Surgical Pathology, and Bacteriology.

Scholarships, &c.—At this University, in addition to six Edgar Allen scholarships of £125 a year for three years, holders of which can take the courses in the Faculty of Medicine, there are 11 scholarships tenable in the Faculty of Medicine. Full particulars as to curriculum, scholarships, &c., may be had on application to the Registrar or to the Dean of the Medical Faculty.

The Medical School.—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c., at extremely moderate prices. The University journal, *Floreamus*, edited by a committee of staff and students, is published each term. The University Halls, "Oakholme," Clarkehouse-road, and "Tapton Cliffe," Fulwood-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained of the tutor for women students.

Clinical Instruction.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes. These are as follows: The ROYAL INFIRMARY (Secretary, Mr. J. W. Barnes), containing 351 beds, with an annual average number of over 5100 in-patients, over 16,000 out-patients, and over 19,000 casualties: the Royal Hospital (Sec., Mr. J. W. Robinson), with 234 beds, and an annual number of 3600 in-patients, over 30,000 out-patients, and over 16,000 casualties: and the Jessop Hospital for Diseases of Women, with 91 beds, over 1000 in-patients, and over 2300 out-patients: also a Maternity department, with about 700 in-patients per annum and about 250 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (600 beds) and on Mental Diseases at the South Yorkshire Asylum (1691 beds). For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 585 beds for the treatment of medical, surgical, and special cases. There are special departments for the treatment of Diseases of the Eye at each institution, with wards assigned to them. In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. Instruction is also given at the South Yorkshire Asylum (1691 beds). The department of Pathology and Bacteriology in the University is fitted with every requirement for the most advanced work in these subjects.

Fees.—The Medical Composition Fee is £38 a year for each of the five years.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics, of which three shall have been passed in the University, and two of these three subsequent to pass in the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). Parts I. and II. may be passed separately or together.

The Final Examination.—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). The subjects included in Part II. may be taken in two groups—viz., Group I., Surgery and Obstetrics; Group II., Medicine, Public Health, Special Pathology, Forensic Medicine, and Toxicology. Candidates may pass Parts I. and II. together, or separately, and the two groups of Part II. may likewise be taken together or separately. Forensic Medicine and Toxicology may be taken either with Part I., or with Group II. of Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery. The degree may be taken also in General Surgery, and a Special Subject—e.g., Oto-Rhino-Laryngology, Ophthalmology, and Gynæcology.

Clinical Instruction.—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL)

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and St. Anne's-on-the-Sea.—The hospital contains 190 beds and 28 in the Convalescent Home, St. Anne's-on-the-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electro-therapeutic Department. Two Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is a new Orthopædic Department. A special out-patients' day is held on Tuesday mornings at Gartside-street, and a ward at Pendlebury is devoted to cases needing operative treatment. Out-patients are seen daily at 9 A.M. at the Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 72 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Zoology and Botany. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Disease and Diseases of Children; Surgery—Systematic, Clinical, and Practical; Obstetrics, and Gynæcology—Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

These conditions are at present under review in connexion with the recommendations of the General Medical Council.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, may be required to pass an examination.

The first term commences on Oct. 1st. Prospectus, &c., can be obtained from the Academic Sub-Dean of the Medical School.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods may do so on terms which may be obtained from the Clinical Sub-Dean.

Clinical Instruction.—**THE LEEDS GENERAL INFIRMARY**, in connexion with this medical faculty, has accommodation for 632 in-patients, including 88 beds at branch hospitals in the country. During 1922 10,277 in-patients and 41,857 new out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

The First Examination.—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

The Second Examination.—The subjects of the examination are Anatomy and Physiology. Candidates must have completed the second year of professional study.

The Third Examination.—The subjects of the examination are Pathology, Pharmacology, Anatomy and Physiology. Candidates must have completed the Lent Term of the fourth year of professional study.

The Final Examination.—The subjects of the examination are:—Part I.—Forensic Medicine and Public Health; Part II.—Medicine (including Mental places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

1. *Regulations applying to all candidates who passed the required Preliminary Examination in General Education before Jan. 1st, 1923.*

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral and partly practical. These examinations will be held in the months of January, April, July, and September or October unless otherwise appointed. Every candidate must give notice in writing to Mr. F. G. Hallett, O.B.E., Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, W.C., 14 clear days before the day of the examination, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, and Elementary Biology. A candidate may take this examination in two parts at different times (Chemistry and Physics must be taken together until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, and in Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine in any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be *exempt from* examination in those subjects.

The fees for admission to the First Examination are as follows: For the whole examination, First Admission, £10 10s.; re-examination in Chemistry, £3 3s.; re-examination in Physics, £2 2s.; re-examination in Biology, £3 3s. Second Conjoint: This examination is in two parts—viz.: Part I., Anatomy and Physiology: Part II., Materia Medica and Pharmacology. A candidate must have attended at a recognised medical school, lectures on Anatomy, Physiology, and a course of Practical Physiology and Histology, and have dissected for twelve months during the ordinary sessions. He must also attend three months' lectures or demonstrations in Pharmacology and receive instruction in Practical Pharmacy. Part II. may be passed at the same time as Part I., or before or after that part, provided the conditions of admission to the whole examination

cates of study required for the respective parts, provided that the examination is not completed before the expiration of five years *from* the date of passing the Preliminary Examination.

The fees for admission to the *Third* or *Final Examination* are as follows: Third Examination: £21; re-examination in Part I., Medicine, £6 6s.; Part II., Surgery, £6 6s.; Part III., Midwifery and Diseases of Women, £4 4s. Members of English, Scotch, or Irish Universities £5 5s. for first admission to the examination and £36 15s. for the diplomas.

A candidate referred on the *Third* or *Final Examination will not be admitted to re-examination* until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

2. *Regulations applicable to candidates who passed the required Preliminary Examination in General Education on or after Jan. 1st, 1923.*

Students are required to pass a *Pre-Medical Examination* in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognised by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any University recognised by the Board: a Pre-Medical Examination conducted by any of the Qualifying Bodies whose Degrees or Diplomas *are registrable on the Medical Register*: the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board: the Higher Certificates of London, Bristol, Durham Universities, and the Joint Matriculation Board of the Northern Universities. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received *instruction during* 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed. The examination is partly written, partly oral and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months and he must produce evidence of further instruction in the subject or subjects of failure. The fee for the examination have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat, and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well-equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Appointments.—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological and ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate: At the Bristol Royal Infirmary: Four house surgeons, £80 each per annum; two house physicians, £80; two resident obstetric officers, one of whom is also ophthalmic house surgeon, £100 and £80: ear, nose, and throat house surgeon, £80; dental house surgeon, £80. All these appointments are made for six months. From the resident officers a senior resident officer is appointed at a salary of £200. At the Bristol General Hospital: Senior resident medical officer, £250 per annum; casualty house surgeon, £80 per annum; two house physicians, £80 per annum; house surgeon, £80 per annum; special obstetric physician, £80 per annum; house surgeon to special departments, £80 per annum; dental house surgeon, £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship, value £45, open to women only; Two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10*s.*, for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose, and throat, value £14: Lady Haberfield Scholarship, value about 25 guineas: Phyllis Siepman Prize, for proficiency in Diseases of Children, value £50.

Bristol City Senior Scholarships and the Senior Scholarships offered by the counties of Gloucestershire, Somerset, Wilts, Devon, &c., are tenable in the University.

Some of the Fellowships awarded by the Colston Research Society for research in the University are allotted to the Faculty of Medicine.

Daily Post-graduate Study.—For those who are able to devote several hours each day to hospital practice the University offers special facilities for Post-graduate work. Qualified medical practitioners may be appointed as Clinical Assistants for a period of one or more months. They may act as Assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Fee, £3 3*s.* per month.

Post-graduate Clinical Work. — Demonstration courses with weekly lectures are held during May, June, and July. Fee, £2 2*s.* All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

This University has, inter alia, the privilege of granting Degrees in Medicine, and Diplomas in Public Health and Tuberculous Diseases. Preliminary courses of study for the Degrees in Medicine may be pursued at any of the constituent Colleges of the University—viz., at Aberystwyth, Bangor, Cardiff, or Swansea. The Welsh National School of Medicine is situated in Cardiff and is an integral part of the University College of South Wales and Monmouthshire there.

University College of South Wales and Monmouthshire, Cardiff. Welsh National School of Medicine.—This School is staffed on the Unit System, and its Courses of Instruction are open to both men and women students. Students can complete the whole of their curriculum in the School, and qualify for the degrees of M.B., B.Ch. in the University of Wales, and M.B., B.S. in the University of London. Students can also qualify for the Diploma of the Conjoint Board of England. Hospital instruction is given at the Cardiff Royal Infirmary, at the City Lodge Hospital, and at other recognised Institutions. The attention of students about to matriculate is drawn to the numerous entrance scholarships offered for competition at the University College, Cardiff, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. Medical men wishing to prepare for the Diploma in Public Health or the Tuberculous Diseases Diploma of the University of Wales can attend complete courses of instruction in the School. Prospectuses can be obtained on application to the Dean of the Faculty of Medicine, or to the Secretary, at University College, Cardiff.

Clinical Instruction.—ROYAL INFIRMARY (KING EDWARD VII. HOSPITAL), CARDIFF. 450 beds.—SWANSEA GENERAL AND EYE HOSPITAL: Hospital, 262 beds. Departments: Pathological Laboratory; Venereal Diseases Department; Ophthalmic: Ear, Nose and Throat; Women; X Ray and Massage. Convalescent Home, 26 beds.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable

SOCIETY OF APOTHECARIES OF LONDON.

The Primary examination is held quarterly. Part I. Chemistry. Chemical Physics; Practical Chemistry; Biology. Materia Medica and Pharmacy. Part II. includes Anatomy. Physiology. and Histology. This examination cannot be passed before the completion of twelve months Practical Anatomy with Demonstrations. and these subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final examination is held monthly except in September. Part I. Clinical Surgery: Principles and Practice of Surgery, Surgical Pathology. and Surgical Anatomy, Operative Manipulation. Instruments. and Appliances. Part II. Clinical Medicine: Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine. Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology. and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances.

The course of study for the *Final examination*, includes attendance on the Surgical and Medical Practice, with Post-mortem Examinations, at a hospital connected with a medical school for a period of two winter and two summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The course of medical study must extend over five years, and the offices of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Two years must elapse after a candidate has passed the examination in Anatomy and Physiology before sitting for any part of the Final examination.

Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Licence is 20 guineas. Female candidates are admitted to examinations. The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses four hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, 50 beds, London, N.W. 1; Tilbury Hospital, Tilbury Docks, Essex, 21 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds, and the Angas Home, 30 beds. It has also a Dispensary in the East India Dock-road from which patients are transferred to the hospitals. The London School of Tropical Medicine is attached to the Hospital for Tropical Diseases. Sessions commence approximately Sept. 22nd, Jan. 5th, and April 27th. Students must be qualified Medical Practitioners or be in the fifth year of their medical studies. Accommodation for [illegible] Students. Fully equipped Laboratories are provided for the study of Entomology, Helminthology, Protozoology, and General Medical Zoology.

In conjunction with the Fellowship of Medicine arrangements have been made for a short course extended over four weeks. Secretary: Sir P. J. Michelli, C.M.G.

WEST LONDON HOSPITAL, Hammersmith, W. 6.—This hospital has 159 beds, all of which are constantly in use. 2319 in-patients and 38,297 out-patients, whose attendances numbered 191,119, were treated last year. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology. The fees for hospital practice, including lectures, are £4 4s. for one month, £9 9s. for three months, or £22 1s. for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Dr. Henry Simson, at the Hospital. Secretary of the Post-graduate College: Mr. C. Cole. Secretary of the Hospital: Mr. H. A. Madge.

ROYAL NORTHERN HOSPITAL, Holloway-road, N. 7.—This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the honorary staff there are six anæsthetists, pathologist, resident medical officer, two resident house physicians three resident house surgeons, and resident casualty officer. The hospital contains 210 beds, which are fully occupied. There is also a ward for children under five years of age. The large rectangular and circular wards, each of which contains 25 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. There is also a well-appointed physiotherapeutic department. The pathological department has been extended and is under the control of a Director of Clinical Pathology. The Reckitt Convalescent Home at Clacton-on-Sea belongs to the Hospital. It contains 30 beds. Special departments have also been established for the treatment of tuberculosis and venereal diseases. A Hospital of Recovery containing 60 beds has now been established at "Grovelands," Southgate, patients being removed from the main hospital by ambulance five or six days after operation. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patients departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office.

Special Departments.—During the past year special departments have been created in genito-urinary and neurological diseases and a fracture department.

Post-graduate Facilities.—In association with the Fellowship of Medicine two-week "refresher" courses have been arranged for March, July, and November in each year. These will include teaching in general medicine and surgery, and special lectures and demonstrations in special subjects.

Further particulars from the Secretary of the Medical Committee at the Hospital.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. 15.—This hospital is in the midst of a densely populated neighbourhood and contains medical, surgical, gynæcological, and children's wards, having 190 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin

Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s*., for re-examination after rejection in Section I. £6 6*s*., for re-examination after rejection in either part of Section I. £3 3*s*., for re-examination after rejection in Section II. £3 3*s*. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. (*a*) Pathology, including Morbid Anatomy, Morbid Histology and Clinical Pathology. (*b*) Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from Section I. The fee for admission to Section I. is £4 4*s*.; for admission to Section II., Part I., £10 10*s*.; Part II., £10 10*s*.; Part III., £6 6*s*.; and the re-examination fees are respectively £3 3*s*., £6 6*s*., £6 6*s*., and £4 4*s*.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board under the old Regulations, or of the First Examination and Section I. of the Final Examination under the new Regulations may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, and in Tropical Medicine and Hygiene. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, a Colonial, or a Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W.C.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—Every candidate must have attained age of 25 years. He must either have passed the examinations for the licence of the College, or else be a registered medical practitioner who has obtained the degree of Doctor or Bachelor of Medicine at a University recognised by the Censors Board. The examination is directed partly to pathology and partly to the practice of medicine. Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German. Further information may be obtained from the Registrar at the College. The fee for admission as a Member of the College is 40 guineas, except when the candidate for membership is a licentiate of the College, in which case the fee already paid for the licence is deducted from the 40 guineas. The fee for the examination is 6 guineas, which is reckoned as part of the fee for admission in the case of a successful candidate.

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:

THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce and include the examination of patients and the performance of operations on the dead body. The First Examination will in future years be held in June and December and the Second Examination in May and November.

The fees for examination are:—First Examination, first admission 8 guineas, and for each re-admission 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 20 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First and Second Examinations of the English Conjoint Board, of the equivalent examinations in his University, on the production of certificates of attendance upon certain prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

The Primary examination is held quarterly. Part I. Chemistry, Chemical Physics: Practical Chemistry: Biology, Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final examination is held monthly except in September. Part I. Clinical Surgery: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. Clinical Medicine: Medicine, Pharmacology, Pathology, and Morbid Histology: Forensic Medicine, Hygiene, Theory and Practice of Vaccination: and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances.

The course of study for the *Final examination* includes attendance on the Surgical and Medical Practice, with Post-mortem Examinations, at a hospital connected with a medical school for a period of two winter and two summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The course of medical study must extend over five years, and the offices of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Two years must elapse after a candidate has passed the examination in Anatomy and Physiology before sitting for any part of the Final examination.

Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Licence is 20 guineas. Female candidates are admitted to examinations. The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses four hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, 50 beds, London, N.W. 1; Tilbury Hospital, Tilbury Docks, Essex, 21 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds, and the Anne Home, 30 beds. It has also a Dispensary in the East India Dock-road from which patients are transferred to the hospitals. The London School of Tropical Medicine is attached to the Hospital for Tropical Diseases. Sessions commence approximately Sept. [illegible], Jan. 5th, and April [illegible]. Students must be qualified Medical Practitioners or be in the fifth year of their medical studies. Accommodation for 100 Students. Fully equipped Laboratories are provided for the study of Entomology, Helminthology, Protozoology, and General Medical Zoology.

In conjunction with the Fellowship of Medicine arrangements have been made for a short course distributed over four weeks. Secretary: Sir P. J. Michelli, C.M.G.

WEST LONDON HOSPITAL, Hammersmith, W. 6.—This hospital has 159 beds, all of which are constantly in use. 2319 in-patients and 38,297 out-patients, whose attendances numbered 191,119, were treated last year. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology. The fees for hospital practice, including lectures, are £4 4s. for one month, £9 9s. for three months, or £22 1s. for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Dr. Henry Simson, at the Hospital. Secretary of the Post-graduate College: Mr. C. Cole. Secretary of the Hospital: Mr. H. A. Madge.

ROYAL NORTHERN HOSPITAL, Holloway-road, N. 7.—This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the honorary staff there are six anæsthetists, pathologist, resident medical officer, two resident house physicians, three resident house surgeons, and resident casualty officer. The hospital contains 210 beds, which are fully occupied. There is also a ward for children under five years of age. The large rectangular and circular wards, each of which contains 25 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. There is also a well-appointed physiotherapeutic department. The pathological department has been extended and is under the control of a Director of Clinical Pathology. The Reckitt Convalescent Home at Clacton-on-Sea belongs to the Hospital. It contains 30 beds. Special departments have also been established for the treatment of tuberculosis and venereal diseases. A Hospital of Recovery containing 60 beds has now been established at "Grovelands," Southgate, patients being removed from the main hospital by ambulance five or six days after operation. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patients departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office.

Special Departments.—During the past year special departments have been created in genito-urinary and neurological diseases and a fracture department.

Post-graduate Facilities.—In association with the Fellowship of Medicine two-week "refresher" courses have been arranged for March, July, and November in each year. These will include teaching in general medicine and surgery, and special lectures and demonstrations in special subjects.

Further particulars from the Secretary of the Medical Committee at the Hospital.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. 15.—This hospital is in the midst of a densely populated neighbourhood and contains medical, surgical, gynæcological, and children's wards, having 190 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin

Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s*., for re-examination after rejection in Section I. £6 6*s*., for re-examination after rejection in either part of Section I. £3 3*s*., for re-examination after rejection in Section II. £3 3*s*. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. (*a*) Pathology, including Morbid Anatomy, Morbid Histology and Clinical Pathology. (*b*) Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from Section I. The fee for admission to Section I. is £4 4*s*.; for admission to Section II., Part I., £10 10*s*.; Part II., £10 10*s*.; Part III., £6 6*s*.; and the re-examination fees are respectively £3 3*s*., £6 6*s*., £6 6*s*., and £4 4*s*.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board under the old Regulations, or of the First Examination and Section I. of the Final Examination under the new Regulations may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, and in Tropical Medicine and Hygiene. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, a Colonial, or a Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W.C.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—Every candidate must have attained e age of 25 years. He must either have passed the examinations for the licence of the College, or else be a registered medical practitioner who has obtained the degree of Doctor or Bachelor of Medicine at a University recognised by the Censors Board. The examination is directed partly to pathology and partly to the practice of medicine. Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German. Further information may be obtained from the Registrar at the College. The fee for admission as a Member of the College is 40 guineas, except when the candidate for membership is a licentiate of the College, in which case the fee already paid for the licence is deducted from the 40 guineas. The fee for the examination is 6 guineas, which is reckoned as part of the fee for admission in the case of a successful candidate.

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:

THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce and include the examination of patients and the performance of operations on the dead body. The First Examination will in future years be held in June and December and the Second Examination in May and November.

The fees for examination are:—First Examination, first admission 8 guineas, and for each re-admission 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 20 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First and Second Examinations of the English Conjoint Board, of the equivalent examinations in his University, on the production of certificates of attendance upon certain prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

throughout the year by members of the medical staff. Clinical assistants are appointed to the physicians in the out-patient department and clinical clerks to the physicians in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital is open to post-graduates and students and special arrangements have been made with the West London Hospital by which post-graduates can attend both hospitals for a combined fee. Dean of the Medical School: Dr. L. S. Burrell, from whom particulars of lectures, clinical appointments, and hospital practice can be obtained.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E. 2.—During the past year 1131 in-patients have been treated in the wards. The out-patients treated during 1923 numbered 10,056. Special Departments: Surgical, Laryngological, Radiological, Pathological, Electro-Cardiographic. Assistants are appointed to the Clinics, and a limited number of research workers to the Pathological Department. The In-patient staff visit generally in the afternoon; Out-patients at 2 p.m. The Post-Graduate Association is open to graduates on payment of fee of 1 guinea per annum, which entitles them to attendance at clinics, post-mortem demonstrations, and operations. Special demonstration and lecture courses are provided, particulars of fees for which can be obtained from the Dean. A club room is also provided. Application for prospectus, &c., should be made to the Dean. Graduates desiring Assistantships in any department should apply to the head of the Department. Physicians to In-patients: E. H. Colbeck, Clive Riviere, A. G. Levy, A. J. Scott-Pinchin, F. G. Chandler, Sir Percy Bassett-Smith; Surgeon: W. H. C. Romanis; Laryngologist: W. G. Howarth; Physicians to Out-patients: J. B. Alexander, J. B. Christopherson; Electro-Cardiographic Department: A. J. Scott-Pinchin; Radiologist: (Vacant); Pathologist: S. R. Gloyne; Assistant Pathologist: D. S. Page; Dental Surgeon: W. Elder. Tuberculosis Dispensary (Boroughs of Bethnal Green and part Hackney). Tuberculosis Officers: H. T. Howell and F. W. Hamilton. Other information from the Secretary of the Hospital.

Royal Chest Hospital (for all affections of the heart and lungs), City-road, E.C. (80 beds). Branch of the Royal Northern Hospital, Holloway.—This hospital provides accommodation for 80 in-patients. Expenditure for 1923, £14,095 18*s.* 3*d.*; income, £12,812 17*s.* 3*d.* The attendance of out-patients averages 30,000 annually. Secretary: Mr. G. G. Panter.

The Mount Vernon Hospital for Tuberculosis and Diseases of the Lungs and Heart, Northwood, Central Out-patient Department, Fitzroy-square, W.—The hospital contains 150 beds, Medical and Surgical; 50 beds reserved for children requiring surgical aid. Number of in-patients, 464: out-patients, 1876. Resident Medical Staff. Clinical Demonstrations are given by the Visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards and in the out-patient department. Secretary: Mr. W. J. Morton.

Queen Charlotte's Maternity Hospital (formerly Queen Charlotte's Lying-in Hospital) and Midwifery Training School, Marylebone-road, N.W.—This hospital receives about 2000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. They also receive valuable instruction in the Ante-natal Department, where over 4000 patients attend yearly. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and maternity nurses are received and specially trained. A Residential College provides accommodation for five men at a time, students and qualified practitioners, and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council. Women students are received. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

Hospital for Women, Soho-square, W.—The teaching in connexion with the above hospital has been greatly extended, and is available for Post-Graduates only, in limited numbers. Every facility is afforded them, by the teaching staff, of obtaining experience in diagnosis and treatment of Gynæcological diseases. The hospital contains 68 beds, and the out-patient attendances are over 14,000 per annum. Operations take place daily at 2 o'clock except on Saturdays. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can also be gained in the treatment of malignant disease by means of radium. Incorporated with the hospital is the London School of Gynæcology, comprising attendance in Out-patient Department, operating theatre, clinical lectures, and X ray treatment. For further particulars apply to the Secretary.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. The fees, payable in advance, are £3 3*s.* for three months. Full particulars may be obtained on application to the Secretary at the hospital. There are 70 beds. Secretary: Mr. G. H. Hawkins.

East London Hospital for Children and Dispensary for Women, Glamis-road, Shadwell, E. —The hospital maintains 130 cots, and on an average 245 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to Mr. W. M. Wilcox, the Secretary.

The Hospital for Sick Children, Great Ormond-street, W.C. 1, contains 244 beds. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to eight medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Fees for hospital practice, one month, £2 2*s.*; three months, 5 guineas; perpetual ticket, 10 guineas. Clinical Clerks, 1 guinea for one month. Ophthalmological Clerkships.—Clinical Clerks are appointed once a month. Fees £1 1*s.* for one month's attendance. Pathological Clerkships.—Facilities are afforded for diseases, plastic surgery, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are four resident medical officers, and clinical assistants are appointed under certain conditions. Special intensive post-graduate courses are held at intervals throughout the year. Further particulars in regard to the hospital may be obtained from Mr. E. Gillespie, Secretary to the Medical Committee, 24, Weymouth-street, W. 1; or from Dr. A. J. Whiting, Dean of the North-East London Post-Graduate College, 19A, Cavendish-square, W. 1.

London Temperance Hospital, Hampstead-road, N.W. (Established 1873; Incorporated 1917).—The hospital contains 120 beds. The in-patients in 1923 were 631, and the out-patients and casualties numbered 11,559 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Mondays at 2 P.M., Tuesdays, Wednesdays, Thursdays, and Fridays at 9 A.M.

Hampstead General and North-West London Hospital.—The Hampstead General Hospital (Haverstock-hill) and the North-West London Hospital (formerly at Kentish Town) have been amalgamated since 1907. The Hampstead General Hospital (128 beds—viz., 102 free, 6 isolation, &c., and 20 paying or contributory) accommodates the in-patients from the districts hitherto served by both hospitals. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients department, Bayham-street, Camden Town. Further particulars from the Secretary at the hospital.

South London Hospital for Women, South Side, Clapham Common, S.W.; Out-patient Department: 86-90, Newington Causeway, S.E.—This hospital, officered entirely by medical women, is a general hospital for women, girls, and small children of both sexes, and provides accommodation for 115 patients. All diseases are treated with the exception of acute infectious fevers and mental disease. There are Ophthalmic, X ray and Electrical, Pathological, Physio-Therapeutic, and Dental Departments. The hospital is a centre for the treatment of venereal diseases under the Public Health (Venereal Diseases) Regulations, 1916. The provision of additional facilities for post-graduate training for medical women is one of the special objects of the hospital. The number of in-patients treated during the year 1923 was 1277. At the Out-patient Department in Newington Causeway 9077 new cases were treated during the past year, the total number of out-patient attendances amounting to 36,300. Clinical assistants (qualified women only) are from time to time appointed in the Out-patient Department. Two resident students act as clinical clerks in the surgical wards. Secretary: Miss M. E. Ridler.

French Hospital and Dispensary, Shaftesbury-avenue, W.C.—This hospital, which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language, has 74 beds. The Convalescent Home and Retreat for Aged French People at Brighton contains 61 beds. Secretary: Mr. J. Knecht.

Italian Hospital, Queen-square, W.C.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 50 beds.

German Hospital, Dalston, E. 8.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for others in cases of emergency and accident. It has 154 beds and a sanatorium with 10 beds; also a Convalescent Home at Hitchin.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury, W.C.—The hospital, with the Convalescent Home at East Finchley and branch at Clapham Park, contains 265 beds and cots. The out-patient physicians attend every Monday, Tuesday, Thursday, and Friday at 2 P.M., and the physicians daily. Clinical clerks are appointed under physicians and clinical assistants to out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held three times every year, usually commencing in January, May, and October and lasting eight weeks. Special Courses in Neurological Ophthalmology, Neuro-Pathology, and the Anatomy and Physiology of the Nervous System are given. The Pathological Laboratory is available for special work under the Pathologist. The hospital has been recognised by the Conjoint Board of England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, hospital practice, and fees should be addressed to the Secretary at the hospital.

Hospital for Epilepsy and Paralysis, &c., Maida Vale, W. (85 beds).—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. Secretary and General Superintendent: Mr. H. W. Burleigh. The out-patient department is open every week-day except Saturday at 2 P.M.

West End Hospital for Nervous Diseases.—Out-patient Department, Welbeck-street, W.; In-patient Department, Gloucester Gate, Regent's Park, N.W.; 76 beds, over 47,000 out-patient attendances. Complete reconstruction has recently been effected and the hospital offers all facilities for instruction in Neurological subjects. A series of clinical demonstrations, apart from the general practice of the hospital, is held regularly each session, and the hospital is coöperating with the Fellowship of Medicine in the programme of special post-graduate teaching organised by the Association. The Savill Memorial Prize (value £15) and Medal are offered annually for competition among post-graduate and undergraduate students who have attended at the hospital. For further particulars apply to C. C. Worster-Drought, M.D. (Dean), or to J. P. Wetenhall, B.A., Secretary, 73, Welbeck-street, W. 1.

Bethlem Royal Hospital, St. George's-road, S.E.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They are permitted to reside in the hospital for a term generally not exceeding six months, commencing May 1st and Nov. 1st, and are provided with apartments, complete board, attendance, laundry, and a salary at the rate of £100 per annum. They are under the direction of the Physician Superintendent and are elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive clinical instruction in the wards of the hospital and qualified practitioners and other students may attend for a period of three months on payment of a fee. A Department for Nervous Diseases has been instituted in a building quite apart from the main hospital. Neurological and early mental cases are dealt with. A Course of Lectures and Practical Instruction for the Diploma in Psychological Medicine granted by the various Universities, will commence in the middle of September. For particulars apply to the Physician Superintendent.

Hospital for Consumption and Diseases of the Chest, Brompton.—The hospital contains 333 beds. The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six house physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. An additional month may be spent at the Sanatorium. Pupils are admitted to the practice of the hospital: terms £1 1*s*. for one month; three months, £2 2*s*. Clinical Demonstrations are given

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, St. Pancras, W.C.—This hospital has 40 beds and clinical teaching is given daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on refraction and other subjects, to meet the requirements of the Conjoint Board for the D.O.M.S., and of the University of London for the M.S. in Ophthalmology, are given during the winter months, commencing in October. The out-patient work begins at 1 o'clock, and operations are performed daily between 2 and 4 o'clock. This school is recognised as a teaching institution by the Universities of London and Oxford, and the Conjoint Board of the Royal Colleges of Surgeons and Physicians. The school has also undertaken to receive a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. Secretary: H. R. S. Druce.

WESTERN OPHTHALMIC HOSPITAL, Marylebone-road, N.W.—16 beds. Out-patient attendances, 30,264. Both In-patient and Out-patient Departments of this Hospital are open to medical graduates. Fees £1 1s. per three months. Honorary Secretary: H. W. Burleigh.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, London, W. (founded 1857).—The practice of the hospital, both in the wards and out-patient department, is open daily to post-graduates and others, and will be found valuable by those seeking the higher qualifications—e.g., M.D., M.R.C.P., &c. Systematic courses of instruction, with lectures and clinical demonstrations, are arranged during the winter and summer sessions; in addition an intensive course, of a fortnight's duration, takes place in January, July, and October of each year. The hospital is fully equipped with all the modern instruments for the investigation of the diseases of the Cardio-Vascular system, and facilities exist for those requiring practical instruction in Electro-cardiography, X Rays, and other graphic methods. Clinical Assistants in the Out-patient Department are appointed from time to time. For further particulars apply to the Dean of the Medical School (Dr. Parsons-Smith), or to the Secretary, at the hospital.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W. (with which is amalgamated the London Throat Hospital, Great Portland-street).—Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 P.M., and on Tuesdays and Fridays from 6.30 to 9 P.M. There is an annual out-patient attendance of over 60,000. Minor operations are performed on Tuesdays, Wednesdays, and Thursdays, at 9.30 A.M. The hospital has been closed for some time owing to rebuilding operations, and the wards and in-patient operating theatres are not yet open. When completed the hospital will contain some 80 beds. Practitioners and medical students are admitted to the practice of the hospital at a fee of £5 5s. for three months, £7 7s. for six months, or £10 10s. for perpetual studentship. From amongst the students junior clinical assistants are appointed periodically. For terms and further information apply to the Dean, Mr. Gilbert Chubb.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.—The practice of the hospital is largely consultative. The hospital is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinique. An Intensive Course of Lectures with demonstrations of cases is given twice yearly—in May and October. Consultations on interesting cases take place on the second Wednesday in each month at 4 P.M. Clinical Assistants are appointed and are expected to hold office for at least three months. They are required to attend twice weekly at 1.30 o'clock for the afternoon, and at 4.30 o'clock for the evening Clinics. Full syllabus can be obtained on application to the Dean.

THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital is in Fitzroy-square, W. The Out-patient Department is opened daily (Saturdays excepted) at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, and Thursdays at 10 A.M. Fee for one month's attendance at the hospital £3 3s., and for three months £5 5s. Clinical Assistants are appointed as vacancies occur, and have responsible duties. Applications should be made to the Secretary, L. L. Phillips.

ROYAL EAR HOSPITAL.—This hospital is now the Ear, Nose and Throat Department of University College Hospital. All out-patient clinics are now held at University College Hospital in Gower-street, but ward visits and operations by the staff take place each afternoon (except Fridays and Saturdays) at Dean-street.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C. (Founded 1835.)—The hospital contains for men and women 54 beds. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Average out-patient attendances, 4000 per year. Average in-patients, 675 per year.

ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES, Henrietta-street, Covent Garden. Established 1860. New Hospital opened 1882.—The hospital contains 30 beds for men and 2 beds for women and children. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, excepting that the only out-patient clinic open to medical women is that held at 2 P.M. Fridays for women and children, and to the operations in the theatre on Mondays at 2.30 P.M., and Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 30; average out-patients seen daily, 100.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, AND THE LONDON SCHOOL OF DERMATOLOGY, 49, Leicester-square, W.C. 2.—The in-patient department, 40 beds, is at 262, Uxbridge-road, W. 12. The out-patient practice is open to the medical profession every day at 2 and every evening (except Saturday) at 6. At all clinics demonstrations on the different diseases presenting themselves are given. Venereal Diseases, under the Government scheme, are admitted at all clinics. The X ray Department is open on Monday, Tuesday, Thursday, and Friday afternoons. The Chesterfield Lectures are given on Tuesdays and Thursdays at 5 P.M., October to March, commencing Oct. 7th., with an introductory lecture by Dr. James H. Stowers. At the end of the course the Chesterfield medal may be competed for by those who have attended three-fourths of the lectures. Special laboratory courses in Pathology and Bacteriology of the Skin may be arranged for. For fees and further information apply to the Dean, Dr. M. G. Hannay.

LONDON LOCK HOSPITAL AND HOME (Founded 1746).—In the Institution at Harrow-road, W. 9, there are 202 beds, and 532 in-patients and 7697 (attendances) out-patients were dealt with in 1923. In the Male Department and Out-patient Department in Dean-street, Soho, W., there are 42 beds, which during 1923 accommodated 384 patients. 90,483 (attendances) out-patients were made in the various departments. 3064 injections of substitutes for salvarsan, &c., were made in 1923. Male patients are seen at 91, Dean-street on Mondays and Tuesdays from 1 to 2 P.M., and from 6 to 8 P.M.; on Wednesdays from 6 to 8 P.M.; on Thursdays, 1 P.M. (male out-patients), 5 P.M. (female patients); on Fridays from 5 to 7 P.M. (male patients); and on Saturdays from 2 to 4 P.M.

obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology in the Pathological Laboratories. Clerks attend for about four hours daily. Fees: For one month, £3 3*s.*; for two months, £5 5*s.*; for three months, £6 6*s.* A reduction is made in the case of those already holding tickets for general attendance at the hospital. Time so spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, and by the Conjoint Board for England as part of the approved curriculum for students entering for a final examination. These appointments are open to students of all recognised medical schools. In addition, special lectures in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily. Details may be obtained by application to the Dean or Secretary at the hospital. The medical school is a constituent part of the new London Post-Graduate Association. Secretary: Mr. James McKay.

Evelina Hospital for Sick Children, Southwark Bridge-road, S.E.—This hospital contains 76 cots and a very extensive Out-patient Department. Clinical assistants (either sex), to work with the Honorary Medical Staff for Out-patients, may be appointed quarterly for a period of three months; there is no salary attached to these posts; but, on the other hand, no fees are charged.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—The hospital contains 130 beds and has a large out-patient department (over 1400 weekly); the home at Broadstairs has 50 beds. Out-patients are seen as under:—Diseases of the Eye: Tuesday, 2 p.m. Diseases of the Skin: Monday, 1.45 p.m. Whooping-cough Cases: Friday, 2 p.m. Dental Cases: Thursday, 1.30 p.m. Medical and Surgical Cases: Mornings at 9.30 and 11.30. Accidents and urgent cases are admitted at any time. Secretary: Mr. D. St. John Bamford.

A Private Nursing Home for Children is now open at 29, Tite-street, in connexion with and adjacent to the hospital. Terms: £1 1*s.* per day or £5 5*s.* per week. Application for admission should be made to the Secretary. Patients must be under the care of a consultant of one of the hospitals of London, and the question of payment for his fees is a matter of arrangement between him and the child's parents.

Queen's Hospital for Children (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E. 2. (Telephone 305 and 534 Dalston.) For the sick children of the poor under 14 years of age. Established 1867. 134 beds in London and 36 at the seaside branch, "Little Folks" Home, Bexhill.—During the past year 1786 in-patients and 37,901 out-patients (attendance 129,649) were received. The surgeons attend on Monday, Tuesday, and Friday at 9 a.m., and on Thursday at 1.30 p.m.; the physicians daily at 1.45 p.m., except Saturday, and also Wednesday and Friday, 9.30 a.m., as well as 1.45 p.m. Whooping-cough Physician: Saturday, 9.30 a.m. The practice of the hospital is open to students by arrangement with the medical staff. Post-Graduate instruction in Children's Diseases, Lectures and Demonstrations, August 11th to 23rd. Skin Physician: Friday, 1.30 p.m. Ear, Nose, and Throat Surgeons: Monday, Tuesday, and Thursday, 9.30 a.m. Eye Surgeon: Wednesday, 1.30 p.m. X ray department open every day. Radiologist attends Monday, Tuesday, Wednesday, and Friday, 2 p.m. Dental department every morning, 9.30, except Saturday; also on Tuesday and Friday, 2 p.m. Massage department daily, morning and afternoon (except Saturday afternoon). Applications should be made to the Secretary, Mr. T. Glenton-Kerr.

Belgrave Hospital for Children, Clapham-road, S.W.—Clinical Assistants (men or women) are from time to time appointed to the members of the Visiting Staff attending in the Out-patient Department at this hospital, and facilities are given for attendance in the wards.

Alexandra Hospital for Children with Hip Disease (late of Queen-square, W.C.), Kettlewell Home, Swanley, Kent (in connexion with St. Bartholomew's Hospital).—At this hospital cases of hip-disease, spinal caries, and tuberculous diseases of other bones and joints are treated. Students who have obtained a recommendation from their teachers can attend to see the practice. In-patients, Swanley, Kent; Out-patients, St. Bartholomew's Hospital; Fridays, 1.30 p.m. Apply for particulars to the Dean of the Medical College, St. Bartholomew's Hospital, London, E.C. 1.

Royal London Ophthalmic Hospital (Moorfields, 1804–1899), City-road, E.C. 138 beds.—This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. Last year there were 2601 in-patients, the out-patients were 50,079, of whom 43,521 were new out-patients, and the attendances were 120,552. Operations are performed daily from 10 a.m. to 1 p.m., and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3*s.*; perpetual, £5 5*s.* Special courses of instruction, which extend over a period of five months, are given by members of the Surgical Staff; beginning in October and March. A composition fee of 24 guineas (£25 4*s.*) will entitle students to a perpetual ticket, and will admit them once to all the lectures and classes and to the examination for the hospital's full certificate. A special course is also held in the preliminary subjects (Anatomy, Physiology, and Optics) for the various degrees in Ophthalmology. The fee for this course is 12 guineas. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary Superintendent.

Royal Westminster Ophthalmic Hospital, King William-street (next door to Charing Cross Hospital), Strand, W.C. 2.—The hospital contains 42 beds. Out-patients, who number over 14,000 annually, are seen daily at 1 p.m., and operations are performed in the theatre at 3 p.m. The practice of the hospital is open to both men and women practitioners and students. Clinical evenings, at which interesting cases are shown and discussed, are held twice each term at 8 p.m. on the second Tuesday of the month. In addition to the ordinary clinical instruction, a systematic course of Lectures and Practical Classes commences in October and May. Lectures in this course are given daily (except on Saturday) at 4.30 p.m., including all subjects required by candidates for the D.O.M.S., R.C.P. & S. Eng., Part II., and practical instruction is given in Operative Surgery and Ophthalmic Pathology and Bacteriology. A corneal microscope has recently been purchased and instruction in the Microscopy of the Living Eye can now be obtained. Fees: One month, £1 1*s.*; three months, £2 2*s.*; six months, £3 3*s.*; perpetual, £5 5*s.*; composition fee for perpetual ticket and attendance at classes (except Operative Surgery and Pathology, for which fee in each case is £2 2*s.* per course), £10 10*s.* Students of the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant, and senior or junior clinical assistant. Full details can be obtained on application to the Dean.

Royal Eye Hospital, St. George's-circus, Southwark, S.E. 1.—There are 40 beds and 2 cots. In 1923 there were 51,958 attendances in the Out-patient Department, the new patients being 21,892. The daily average of attendances was 172 patients. In-patient admissions numbered 840. Clinical instruction is given to students and post-graduates daily at 2.30 p.m., and Lectures, Demonstrations, and Laboratory Classes are arranged in preparation for examinations in Ophthalmology. Post-graduate students are eligible for appointment as Clinical Assistants and as Refraction Officers. Dean: Mr. A. D. Griffith.

buildings and alterations. A new Out-patient Department, costing £12,000, a new Children's Ward of 30 beds, a new Pathological Department, and a second large Operation Theatre are amongst the structural improvements already completed. The whole institution is now equipped in a thoroughly up-to-date manner. An Electro-Cardiograph is just about to be installed. Secretary and House Governor: Mr. W. Stevenson.

HULL ROYAL INFIRMARY, Hull.—This Hospital contains 266 beds, and since its establishment in 1782 until the erection of the circular wards in 1907 has undergone steady additions and improvements, including an up-to-date pathological department recently added. A branch convalescent home at Withernsea is a special feature of the charity.

LEICESTER ROYAL INFIRMARY, Leicester.—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 233 beds, and at the Children's Hospital in connexion 70; venereal diseases, 17. A new wing containing 100 beds has recently been added: total 420 beds. A reconstruction scheme has been carried out, and £250,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, and self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Open-air balconies on all three floors are a feature. A central sterilising department has been provided. Pathological Laboratories and post-mortem rooms have recently been opened at a cost of £11,000, also an orthopædic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home has recently undergone enlargement by 60 bedrooms. The 150th anniversary of the Institution has recently passed and an effort was made to raise a sum of £100,000 in commemoration. Funds are being raised for the foundation of a City University, and a splendid site was presented by the late Mr. T. Fielding Johnson, J.P., an ex-chairman of the Royal Infirmary. There are eight resident salaried medical officers at the Infirmary—viz., four house surgeons, one house physician, one assistant house physician, and two dressers. The posts are usually filled half-yearly and afford exceptional opportunities for post-graduate experience and senior students. Dressers are given an honorarium. Students are encouraged to make full use of the facilities which exist to gain clinical knowledge in the wards. The hon. medical and surgical staff are wishful of affording instruction in a variety of conditions which an active and well-equipped general hospital in a large commercial centre is called upon to treat. A post-graduate course of lectures is arranged annually, and also clinical classes are held for those graduates preparing for the M.D. and M.R.C.P. A new Residency for Doctors has been erected. Chairman of the Board: Mr. J. G. Pickard. Deputy Chairman ot the Board: Lieut.-Col. C. F. Oliver, D.L., V.D. House Governor and Secretary: Mr. Harry Johnson, from whom information as to prospective vacancies on the Resident Staff may be obtained.

NORTHAMPTON GENERAL HOSPITAL, Northampton.—Two new wings were opened in 1904 and the old buildings entirely renovated and rearranged. The number of beds is 231, 34 of which are occupied by discharged disabled pensioners. Non-resident pupils received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10s. Pupils can be received at any time. An up-to-date Pathological Laboratory has recently been erected.

NORFOLK AND NORWICH HOSPITAL, Norwich.—This hospital has at present 300 beds. There is a convalescent home at Cromer. Students are admitted to the practice of the Hospital for a fee of £5 5s. for six months. Secretary: Mr. Frank Inch.

NOTTINGHAM GENERAL HOSPITAL.—There are at this hospital 310 beds available for medical and surgical patients, and 46 beds are in the detached ward known as "The Cedars" Convalescent Hospital. The Medical and Surgical Staffs consist of 2 Honorary Consulting Physicians; 3 Honorary Consulting Surgeons, 1 Honorary Consulting Physician in Venereal Diseases; 3 Honorary Physicians; 4 Honorary Surgeons; 2 Honorary Assistant Physicians; 2 Honorary Assistant Surgeons; 2 Honorary Aural Surgeons; 1 Honorary Dermatologist; 2 Honorary Anæsthetists; 1 Honorary Surgeon Dentist and 1 Honorary Medical Officer in Charge of X ray and Electro-therapeutic department. The Resident Medical Staff consists of 2 House Physicians, 4 House Surgeons, 1 Aural House Surgeon, and 1 Casualty Officer. The special departments are the Ear, Nose and Throat, Skin, Dental, Massage and Exercise, X ray, Orthopædic, Electro-therapeutic. House Governor and Secretary: Mr. P. M. MacColl. Assistant Secretary: Mr. T. H. G. Gartland.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—This hospital contains 190 beds (14 of which are for Venereal Diseases in a separate building). There is also an Out-patient Venereal Diseases Clinic. There is a Pathological Laboratory, special departments for X ray and Electro-therapeutics, an Out-patient Orthopædic Clinic under the Ministry of Pensions, and a civil Orthopædic Department. Pensioners are received as in-patients. The hospital is a centre for the treatment of Tropical Diseases.

ROYAL HOSPITAL, Portsmouth (founded 1847).—The number of beds is 160. There are X ray and Massage Departments. The hospital is a preparatory school of Medicine and Surgery; the attendance of pupils is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

ROYAL BERKSHIRE HOSPITAL, Reading.—This hospital, which contains 220 beds, was enlarged in 1912, and includes an Out patient Department, a Casualty Department, an X ray Department, Electro-therapeutic and Massage Department, a V.D. clinic, a Laboratory, an Eye Theatre, Eye Wards, and Motor and Horse ambulances. The hospital is approved by the General Nursing Council as a Training School for Nurses. Post-Graduate Lectures are given.

SALISBURY GENERAL INFIRMARY, Salisbury.—This hospital contains 141 beds. The daily average number of in-patients is 116; number of new out-patients, 4827; number of out-patient attendances, 25,129, including 9276 casualties, 1579 medical and surgical out-patients, 505 ear, nose and throat cases, 1183 ophthalmic cases, 717 dental cases, 3360 venereal cases, 1028 X ray cases, and 7481 massage and electrical cases. Special features: Maternity and ante-natal, ophthalmic and private wards. House Governor and Secretary: John S. Birbeck.

ROYAL SALOP INFIRMARY, Shrewsbury.—This hospital has 130 beds. In-patients, 2524; out-patients, 1786; out-patients' attendances, 22,310; accidents and casualties, 4035; dental cases, 645. A site has been purchased adjoining the present Infirmary structure, and it is proposed to erect an annexe for women and children thereon. Secretary: Mr. Alfred Sugden. The above statistics refer to the 18 months' period July 1st, 1922, to Dec. 31st, 1923.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL, Southampton.—This hospital contains 130 beds. In-patients, 3059; out-patients, 12,987. Secretary: Mr. T. A. Fisher Hall.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford (established 1766).—This hospital has 87 beds. In-patients, 958; out-patients (new cases), 2610. Secretary: Lieutenant A. E. Collins.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—This hospital has 158 civilian beds. Secretary: Mr. Herbert Maslen.

(males). Pathological Department, daily at 6.30 P.M. Intravenous injections are given at every clinic. Female clinics are held at 283, Harrow-road, Paddington, on Mondays at 10 A.M., Tuesdays, Wednesdays, and Thursdays at 2 P.M. to 3 P.M. The new female out-patients department is open all day long from 9 A.M. to 8 P.M. Irrigations for males are given daily 8 A.M. to 10 P.M. For females Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays at 11 A.M. to 1 P.M., at 91, Dean-street. The Hospital is linked up with the Fellowship of Medicine, and special courses of lectures are held in February, May and November each year. Application for tickets should be made direct to the Secretary. Only a limited number of practitioners and students are permitted to attend the Female Lock Hospital, and application should first be made to Major Corbett (Dean) at the Male Lock Hospital; or to the Secretary, Hy. J. Eason, at the Chief Offices, 283, Harrow-road, W. 9.

ENGLISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

Under this heading we include all the hospitals which are recognised by the English Royal Colleges for a part of the required attendance on medical and surgical practice, for medical clerkships, and surgical dresserships. The list includes nearly every hospital of a general character in the country having more than 150 beds, though occasionally a large hospital is omitted because equally good opportunities are afforded to students at other institutions in its neighbourhood, while a small hospital may be included because no such facilities for study are present elsewhere. The list is arranged alphabetically as to the town where the hospital is located. Most of the larger general hospitals of the kingdom have already been noticed in connexion with the Universities.

Bath Royal United Hospital, Bath.—This hospital contains 206 beds, 72 of which are situated in Combe Park, Bath, and are for *paying patients* only, and possesses X ray, Massage, Bacteriological Departments, a new Pathological Laboratory, and a fine library. Secretary: Mr. J. M. Sheppard. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men), from 5 to 6.30 P.M., and Ear, Throat, and Nose Clinics on Thursdays, at 4 P.M.

Bedford County Hospital, Bedford.—This hospital has 109 beds, including 15 beds in the paying wards, X ray and Pathological Departments. There is in connexion with the institution a convalescent home (20 beds) at Aspley Heath, nr. Woburn Sands. The hospital is approved by the University of London for the purposes of the M.D. and M.S. Examinations. Secretary: Mr. Beauchamp Wadmore.

Bradford Royal Infirmary, Bradford. — This hospital contains 215 beds. The material passing through the surgical wards consists of major operations, chiefly abdominal, and gynæcological work, and affords excellent facilities for either students or post-graduates. There are special clinics for Orthopædic and Venereal cases. Plans for a new hospital of 382 beds have been adopted, and building operations will be commenced as soon as funds will allow.

Royal Sussex County Hospital, Brighton (225 beds).—This hospital affords ample facilities for students, possessing a large out-patient department, including Ophthalmic, Dental, Dermatological, Gynæcological, X ray, and Orthopædic sections, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years, on payment in advance of a fee, not exceeding 20 guineas, as the Board of Management shall direct.

Kent and Canterbury General Hospital, Canterbury.—The hospital contains 115 beds. Pupils of the staff are admitted to the practice of the hospital. Operations four days of the week. There is an Ophthalmic Department with two wards for in-patients, a Venereal Clinic, an Orthopædic Department, &c. Secretary, Mr. F. P. Carroll.

Coventry and Warwickshire Hospital, Coventry (established 1840).—This hospital contains 241 beds, and a new wing as well as theatre and kitchens have been added. Special clinics are held for diseases of the Eyes, Ears, Nose and Throat; Gynæcology; X ray and Electrical Treatment. There are also V.D. Clinics. Clinical students are received, and there are paying wards. Secretary: Miss R. Hooper.

Derbyshire Royal Infirmary, Derby.—This hospital contains 320 beds. It was founded in 1810, and was entirely rebuilt and enlarged 1892–1915 on the most modern lines at a cost of over £144,000. There is a separate ophthalmic block of 33 beds, a separate children's block of 34 beds, and a special department for gynæcological cases. There are four resident house surgeons, a resident house physician, and an assistant house surgeon and casualty officer. There are also well-equipped orthopædic, X ray, electrical, and venereal diseases departments. Registered medical students are admitted to witness the medical and surgical practice on payment of 10 guineas annually.

Royal Devon and Exeter Hospital, Exeter.—The hospital contains 225 beds (including special children's wards) and has a good library, museum, post-mortem room, and pathological laboratory. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897 and the "Victory" wing for the treatment of discharged disabled soldiers and sailors completed and opened in 1922. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). The Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King. This department is now enlarged to meet the ever increasing work, and now forms one of the most important sections of the hospital. A department was opened in 1917 for the treatment of genito-urinary diseases; there are three sessions per week, two for men at 3 P.M. and 7 P.M., and one for women at 3 P.M.

West of England Eye Infirmary, Exeter.—Secretary: Mr. W. W. Beer. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1923, 3387. A ward is set aside for newly-born babies suffering from infectious eye diseases. The mothers are accommodated with their babies.

Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—This hospital, which was granted the title of "Royal" on the occasion of King Edward VII.'s visit to Gloucester in the year 1909, has 140 beds. Secretary: G. Hurford. In-patients, 1808; out-patients, 9044. An electrical and massage department has been established and venereal clinic opened. Also ear, nose and throat department, X ray department, and dental department.

North Staffordshire Infirmary, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for about 304 patients, including Children's wards, and a special department for the treatment of Diseases of the Eye, a special X Ray and Electrical Department, a special department for the treatment of Diseases of the Ear, Nose, and Throat, a special orthopædic department, and venereal diseases clinics, so that there are excellent facilities for acquiring a practical knowledge of the profession. During the last six years the sum of £35,000 has been spent on new session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The practical classes and laboratories will open and the lectures commence on Oct. 14th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Special courses of instruction for dental students are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £170, payment of which is distributed over the period of study. There is no composition fee.

Post-graduate Courses are conducted in conjunction with the University.

Further particulars regarding the school, also its calendar (price 6*d.*) may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

In connexion with the University and Royal Colleges Post-Graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Clinical Instruction.—ROYAL INFIRMARY, Edinburgh.—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medico-Electrical and X Ray Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student to a life ticket. The appointments are as follows: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

Facilities are given in connexion with the Post-graduate Courses arranged by the Edinburgh University and the two Royal Colleges jointly.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Post-graduate Courses of Lectures are held during the year. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH (with which is incorporated the Edinburgh Eye Dispensary), 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for out-door patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time. A post-graduate course in Diseases of the Ear, Nose, and Throat is held each academic term, commencing in May, October and January, and continuing for six weeks. The next course commences on Oct. 14th, 1924. The class meets at 5 P.M. Tuesdays and Fridays, and the instruction, which is essentially practical, is supplemented by lantern demonstrations. Secretary: Mr. J. P. Watson, W.S., 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health: B.Sc. in Pharmacy; and Ph.D. in the Faculty of Medicine. A Diploma in Public Health (D.P.H.) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required after registration as a medical student in the books of the General Medical Council. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of

WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL, Wolverhampton.—There are 210 beds. Special departments for Children, Infectious cases, Gynæcology, Ear, Throat, and Nose Diseases, Electrotherapeutic and X ray, Venereal Disease, Pathological Laboratory, Dentistry, and Electro-cardiographic Installation. There is an excellent library. The resident officers are a resident surgical officer, resident medical officer, and two house surgeons. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a practical knowledge of their profession. A course of Practical Pharmacy is given by the dispenser. Fees on application. Applications should be made to the Honorary Secretary of the Medical Committee. In 1923, 3537 in-patients and 23,939 out-patients were treated; 3780 operations were performed in the theatres.

WORCESTER GENERAL INFIRMARY, Worcester.—This hospital has 132 beds (temporarily reduced to 70). Pupils are taken by members of the Honorary Medical and Surgical Staff. Number of operations last year 930. New X ray and Electrical and Wolfram Arc Light, Ear, Nose and Throat, and Orthopædic Departments have been erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII. In-patients, 1254; out-patients, 3901. Secretary: Mr. E. J. Holland.

YORK COUNTY HOSPITAL, York.—This hospital contains 180 beds. There are balconies for outdoor treatment, two installations of X ray apparatus, electro-therapeutic and massage department, and clinical laboratory. A Venereal Diseases Clinic is held.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The subjects of the Qualifying examination of the Pharmaceutical Society are:—Part 1: (*a*) Chemistry; (*b*) Physics; (*c*) Botany. Part 2: (*a*) Materia Medica: (*b*) Pharmacy, including Posology and the Translation and Dispensing of Prescriptions; (*c*) the law relating to the keeping, selling, and dispensing of poisons and poisonous substances. Fee, 12 guineas; for each subsequent examination after failure, 3 guineas. The advanced or Major examination (for registration as "pharmaceutical chemist") includes botany, chemistry, physics, practical chemistry, and materia medica. Fee, 3 guineas. The courses of instruction given in the Society's school cover the entire ground for both examinations. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates in Science may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories. Application for admission to the school, or for further information, may be made to the Dean, Prof. Greenish, 17, Bloomsbury-square, London, W.C. 1.

II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course of instruction in Practical Midwifery and have personally conducted at least 12 cases of labour.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teacher as may be recognised for the purpose by the University Court. Of the subjects of study—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than one-half must be taken in the University of Edinburgh, which corresponds to the two years above referred to.

Women are admitted to graduation in medicine under the same conditions as men.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £34 13*s.*, and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £9 9*s.*; for the Second Division (Anatomy and Physiology), £7 7*s.*; for the Third Division (Pathology and Materia Medica and Therapeutics), £6 6*s.*; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Gynæcology, and Forensic Medicine and Public Health), £11 11*s.*

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £21, and the fee to be paid for the degree of Ch.M. is £21.

Post-Graduate Instruction.—Courses of instruction are given for the Degrees of B.Sc. and D.Sc. in Public Health and for the University Diplomas in Public Health, Tropical Medicine and Hygiene, and Psychiatry. These Diplomas are open to approved registered practitioners as well as to graduates in Medicine and Surgery of the University. The University also takes part in the Courses given under the auspices of the Edinburgh Post-Graduate Courses in Medicine. In the departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for candidates for the Degree of Ph.D. whose applications to engage in research have been accepted by the Senatus.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars can be obtained from the Dean of the Medical Faculty.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The practical classes and laboratories will open and the lectures commence on Oct. 14th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Special courses of instruction for dental students are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £170, payment of which is distributed over the period of study. There is no composition fee.

Post-graduate Courses are conducted in conjunction with the University.

Further particulars regarding the school, also its calendar (price 6*d.*) may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

In connexion with the University and Royal Colleges Post-Graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Clinical Instruction.—ROYAL INFIRMARY, Edinburgh.—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medico-Electrical and X Ray Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student to a life ticket. The appointments are as follows: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

Facilities are given in connexion with the Post-graduate Courses arranged by the Edinburgh University and the two Royal Colleges jointly.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Post-graduate Courses of Lectures are held during the year. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH (with which is incorporated the Edinburgh Eye Dispensary), 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time. A post-graduate course in Diseases of the Ear, Nose, and Throat is held each academic term, commencing in May, October and January, and continuing for six weeks. The next course commences on Oct. 14th, 1924. The class meets at 5 P.M. Tuesdays and Fridays, and the instruction, which is essentially practical, is supplemented by lantern demonstrations. Secretary: Mr. J. P. Watson, W.S., 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; B.Sc. in Pharmacy; and Ph.D. in the Faculty of Medicine. A Diploma in Public Health (D.P.H.) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required after registration as a medical student in the books of the General Medical Council. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of

Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases Peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College and must prosecute a course of special study or research for two or three years and give evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject-matter of the thesis.

Fees.—The Fees for M.B. and Ch.B. are £34 13*s*. The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3*s*., £4 4*s*., or £6 6*s*., and the present fee for hospital attendance is £7. The fee for M.D. is £21, and for Ch.M. £21.

The great majority of the students take their hospital course at the Western, Royal, and Victoria Infirmary, and at the district hospitals of the Glasgow Parish Council, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, Insanity, and Electro-diagnosis and Therapeutics. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it certain medical classes for women are conducted under University lecturers appointed by the University Court.

Post-graduate Medical Teaching.—Organised Post-graduate Medical Teaching is now available in Glasgow under the auspices of Glasgow Post-graduate Medical Association. This Association is composed of practically all the Teaching Institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a Board elected periodically by them. The chairman of the Board is Principal Sir Donald MacAlister, and the vice-chairman Sir Hector C. Cameron. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from Dr. James Carslaw, Secretary, Post-Graduate Medical Association, University, Glasgow.

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course. A full list will be found in the University Calendar.

THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.—Courses are given which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Dental Hospital, Glasgow.

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men.

The Carnegie Trust extends its benefactions to students of the Anderson College of Medicine. Full particulars may be obtained from Sir W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. George C. Pringle, M.A., Educational Institute Office, 47, Moray-place, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Walter Hurst, Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

The Winter Session will open on Monday, Oct. 13th, 1924.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The classes in St. Mungo's College qualify for the medical qualifications of the English, Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. The classes are open to male and female students equally. The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £120. Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

QUEEN MARGARET COLLEGE (Women's Department of the University).—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University. Approximately 600 women have now taken the degree of M.B., C.M., or M.B., Ch.B. of the University of Glasgow and 33 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill. Queen Margaret College, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Excellent facilities for clinical work are given in the Royal, Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholar- ships, and fellowships. The Winter Session will open on Oct. 13th. New students of Medicine will be admitted in April, 1925. Applications for entrance at that date should be made before Feb. 1st, 1925.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. St. Mungo's College is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, skin, venereal diseases, burns and septic cases. The wards are open to Women Students. At the Out-door Department the attendances in 1923 numbered over 200,000. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 10 house surgeons, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Classes are held during September in Clinical Medicine, Clinical Surgery, Clinical Gynæcology, Diseases of the Skin, Venereal Disease in the Male, Diseases of the Throat, Nose and Ear, and in Diseases of the Eye. For information regarding fees and other particulars, application should be made to the Superintendent.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 600. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Teeth, Skin, Venereal Disease, and Electro-therapeutics. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also postgraduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course. The fees are as follows:—For Infirmary Attendance, Dispensary, &c.: (*a*) For Perpetual Ticket, £12 12*s.*; (*b*) for Single Term Ticket, £1 11*s.* 6*d.* For Courses of Instruction: (*a*) Six Months or Two Terms, £5 5*s.*; (*b*) Three Months or One Term, £2 12*s.* 6*d.* A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods. Secretary: J. Matheson Johnston, C.A., 87, Union-street.

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow.—This institution, which was founded in 1882. consists of: (1) a hospital at Yorkhill containing 270 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888: and (3) a country branch at Drumchapel, Dumbartonshire, containing 30 cots, opened in 1903. Children treated must not be over 13 years of age, nor suffer from in- infectious diseases. In 1923 there were 5853 patients treated, and there were 74,689 attendances of out-patients. There are one professorship and two lectureships in the University of Glasgow in connexion with the hospital, one professorship and one lectureship on the Medical Diseases of Infancy and Childhood, and one lectureship on Surgery and Orthopædics in Relation to Infancy and Childhood. The lectureships are held by the Visiting Physician, Dr. Leonard Findlay, and one of the Visiting Surgeons, Mr. Alex. MacLennan. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition special facilities are given for post-graduate study. Information with regard to clinical instruc- tion, lectures, demonstrations, post-graduate study, &c., may be obtained from the Med. Superintendent.

THE GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL, Rottenrow.—The new hospital, which was opened in 1908, is in point of size the largest of its kind in Britain and has accommodation for 108 patients. A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Ante- natal Department and an Infant Consultation Clinic. In 1923 5026 normal cases and 2390 abnormal cases were treated by the hospital in the In-door and Out- door Departments. Secretary: Mr. William Guy, 146, Buchanan-street. Full particulars as to fees and accommodation may be obtained from the House Superintendent at the hospital.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, Glasgow.—This hospital, founded in 1886, is the largest purely gynæcological hospital in Great Britain, possessing, as it does, over 90 beds, which will be increased to 160 when building extensions are completed. It offers excellent facilities for clinical instruction in the diseases peculiar to women, treating in the wards and in the out-patient department from 5000 to 6000 cases per annum. Lectures and clinical demonstrations are given by members of the surgical staff to students and to post-graduates; and the hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for coordinating post-graduate medical teaching in all the hospitals. For further information application may be made at the Hospital, or to T. Mason Macquaker, M.A., B.L., Secretary, 149, St. Vincent-street, Glasgow.

GLASGOW LOCK HOSPITAL, 41, Rottenrow.—The hospital contains 83 beds. During 1923 494 patients were admitted to the wards; 20,731 visits were made by out-door patients at the dispensary. A Labour Ward has been added. Classes are held for the clinical instruction of medical students. These classes are now compulsory, and 174 students attended last year. There are also post-graduate classes held. A new lecture room and laboratory is being built. J. Neilson Gray, LL.B., secretary and treasurer, 65, Bath-street, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street, and 131, Wellington-street (30 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions.

In-patients, 855; out- or dispensary patients, 13,541; daily average of attendances, 142·4; total attendances, 39,575. Operations on Wednesdays and Saturdays. This institution is administered by the Royal Infirmary. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

Glasgow Eye Infirmary, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 25,714 and the total number of cases in 1923 was 56,138. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October. Post-graduate Classes are being held.

Glasgow Hospital for Diseases of the Ear, Nose, and Throat, 27 and 28, Elmbank-crescent.—14 beds. New patients, 6374. Attendances at out-patient department 20,348. Admitted to in-door department 440. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School. Secretary: D. N. Mackay, 144, St. Vincent-street, Glasgow.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (L.D.S.).

The Preliminary Examination includes (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects: (α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other approved modern language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of L.L.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years after registering as a medical student. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica and Pathology and Bacteriology and Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical). The combined fee for tuition and clinical tuition is £182, payable in five annual instalments. Additional fees are required for hospital ticket, midwifery cases, laboratory apparatus.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 33 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 20 guineas, and for the degree of Master of Surgery 20 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews.

For further particulars and details as to scholarships and bursaries application should be made to Prof. Charteris, Dean of the Medical Faculty, University College, Dundee.

University College, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

Royal Infirmary, Dundee.—The Infirmary contains 408 beds. In addition to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose and Throat, and of the Skin; and for Clinical Pathology, Radiology, Electro-therapeusis, and Electro-cardiography. An extension providing for new X Ray and Massage Departments and for additional Operation Theatre accommodation is being constructed at a cost of £20,000. Clinical teaching is given to male and female Students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the other Boards of the United Kingdom. Nine Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the Physicians and Surgeons; and Students are appointed as assistants in the pathological department. The fees for Hospital attendance are as follows: For Perpetual Ticket, £12, or if paid in instalments, £12 12*s.*; Ticket for 12 Months, £4 4*s.*; Ticket for 3 Months, £1 11*s.* 6*d.* Further information may be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.). The Degree of Doctor of Philosophy (Ph.D.) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Before commencing his medical studies each student must comply with the following regulations: (1) Every Candidate desiring admission to the Faculty of Medicine must be in possession of the necessary "Certificate of Fitness" issued and attested by the Scottish Universities Entrance Board, 81, North-street, St. Andrews. Forms on which to make application for this Certificate may be obtained from the Secretary to the University of Aberdeen. From and after Jan. 1st, 1921, the Regulations contained in the Ordinances for Degrees in Medicine are revoked, and the following General Regulation made by the Entrance Board is substituted therefor, namely: "That (*a*) the Group Certificates of the Scottish Education Department, or (*b*) the evidence of satisfactory completion in Schools in Scotland of a curriculum of Secondary Education, as attested by the said Group Certificates or otherwise, or (*c*) the Leaving or other Certificates accepted as qualifying for admission to the Universities in the case of applicants for admission from outside Scotland, which shall be deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for graduation in the Faculty of Medicine, shall be the same as those which, under the Regulations for the time being in force, are deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for graduation in the Faculty of Arts or, alternatively, in the Faculty of Science, for Degrees in Pure Science."

Candidates, therefore, before entering on the curriculum for the Degree must: (1) have passed (*a*) the Arts Preliminary Examination, or (*b*) the Science Preliminary Examination, or (2) hold a qualification recognised as exempting from such examination. (3) Have attained the age of 17 years. (4) That they have passed the Pre-registration Examination in Physics and Chemistry.

The following regulations for Pre-registration Courses in Physics and Chemistry have been made by the University of Aberdeen:—

1. Pre-registration Courses in Physics and in Chemistry will be held in the Winter Term and in the Summer Term. The fee for each course is £2 2*s.*
2. The Senatus Academicus has power to grant exemption from attendance on these courses of instruction to students who have completed courses of instruction in Physics or Chemistry in a Secondary School, Technical or University College, Medical School or University, provided that the courses include practical work.
3. Pre-registration Examinations will be held in Marischal College at the end of the Summer Term, immediately before the commencement and at the end of the Winter Term, and at the end of the Spring Term, or at such other times as the University Court, after consultation with the Senatus Academicus, may determine. The Examination Fee is 10*s.* 6*d.* for each subject.
4. The Senatus has power to grant exemption from the Pre-registration Examination to candidates: (i.) who have passed an Examination in Physics and Chemistry for a Degree in Arts, Science, or Medicine at any University in the United Kingdom, or any other University specially recognised for the purpose by the University Court, or (ii.) who have passed an Examination in these subjects which has been previously specially recognised by the University Court as equivalent to the Examination carried out by the University of Aberdeen.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital; they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

The cost, including Matriculation, Class, Degree, and Hospital Fees, for the whole curriculum leading to the Degrees of M.B. and Ch.B. is approximately £240.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institutions, &c.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis must be presented for approval. The fee is £10 10*s.*

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £160 per annum. Prizes and Medals: 13 Gold Medals and Prizes for proficiency in special departments, &c.

Clinical Instruction is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff.

ABERDEEN ROYAL MENTAL HOSPITAL.—Contains, with hospital attached to main institution and agricultural branch, about 950 beds. Clinical instruction is given to students during three months in summer. Clerk and Treasurer, Mr. A. Scott Finnie, 343, Union-street, Aberdeen.

In-patients, 855; out- or dispensary patients, 13,541; daily average of attendances, 142·4; total attendances, 39,575. Operations on Wednesdays and Saturdays. This institution is administered by the Royal Infirmary. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

Glasgow Eye Infirmary, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 25,714 and the total number of cases in 1923 was 56,138. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October. Post-graduate Classes are being held.

Glasgow Hospital for Diseases of the Ear, Nose, and Throat, 27 and 28, Elmbank-crescent.—14 beds. New patients, 6374. Attendances at out-patient department 20,348. Admitted to in-door department 440. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School. Secretary: D. N. Mackay, 144, St. Vincent-street, Glasgow.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (L.D.S.).

The Preliminary Examination includes (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects: (α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other approved modern language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of L.L.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years after registering as a medical student. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica and Pathology and Bacteriology and Forensic Medicine and Public Health: and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical). The combined fee for tuition and clinical tuition is £182, payable in five annual instalments. Additional fees are required for hospital ticket, midwifery cases, laboratory apparatus.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 33 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 20 guineas, and for the degree of Master of Surgery 20 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews.

For further particulars and details as to scholarships and bursaries application should be made to Prof. Charteris, Dean of the Medical Faculty, University College, Dundee.

University College, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

Royal Infirmary, Dundee.—The Infirmary contains 408 beds. In addition to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose and Throat, and of the Skin; and for Clinical Pathology, Radiology, Electro-therapeusis, and Electro-cardiography. An extension providing for new X Ray and Massage Departments and for additional Operation Theatre accommodation is being constructed at a cost of £20,000. Clinical teaching is given to male and female Students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees of diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

The Fellowship.—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly vivâ voce, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiateship of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to appear for examination must be given by the candidate to Mr. D. L. Eadie, 49, Lauriston-place, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, otherwise a special application, with six testimonials, must be made to the President and the Council of the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held as separate qualifications.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £30, £10 of which sum are returned to any successful candidate who already holds the Licence of the Faculty. An additional sum of £20 is required in the case of candidates resident within seven miles of Glasgow. In certain circumstances Fellows may be elected as a mark of distinction.

Licence.—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

The hospitals which are recognised by the Scottish Conjoint Board as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 432) and the Irish Conjoint Board (see p. 453).

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—In order to join the School of Physic students pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 1st.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March and in June. Courses in preparation for it may be taken in the School of Physic. On passing this examination Medical students should register as such with the General Medical Council.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Botany, Zoology, Physics and Practical Physics; Systematic, Descriptive and Applied Anatomy; Chemistry and Practical Chemistry; Histology, Physiology, Practical and Applied Physiology; Practice of Medicine; Midwifery and Gynæcology, Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Surgery and Operative Surgery; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy, Physiology, and Organic Chemistry; and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Hygiene and Jurisprudence, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth year.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also read and discuss a thesis before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

SCOTTISH CONJOINT BOARD.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months: Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months; Practical Physiology, three months; Materia Medica, three months; Pathology (including Practical Pathology), nine months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months; Gynæcology, one course of not less than 13 meetings; Diseases of Children, one course of not less than 13 meetings; Medical Jurisprudence and Public Health, three months. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or act for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months: Gynæcology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c. The fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject.

There are four periods of examination annually: During the ensuing period thrice in Edinburgh and once in Glasgow, in 1924–25. The Registrar in Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom further particulars concerning fees can be obtained.

For students registered with the General Medical Council after Jan. 1st, 1923, more extensive Regulations are in force, and candidates applying for Regulations should state date of registration.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence. The fee for the Membership is £36 15*s.*, 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected from the ranks of the *Members.* The fee is £64 18*s.*

ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any various athletic clubs, the last of these holding a public meeting once in each year in the Mardyke grounds.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who are candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council. For information as to the conditions and courses of the Matriculation Examination application may be made to the Registrar, National University, Dublin.

Admission of Medical Students.—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may be admitted to the rank of fourth-year students.

Residence of Students.—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, the Cork Fever Hospital, the Cork District Hospital, and the Cork Ear, Eye, and Throat Hospital.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, Professor A. E. Moore.

*South Charitable Infirmary and County of Cork General Hospital** (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for nine months, £12 12*s.*; for six months, £8 8*s.*; for three months, £4 4*s.* Two resident pupils will be appointed by competitive examination.

Cork North Charitable Infirmary and County and City of Cork General Hospital (112 beds).—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior students on two days weekly. Fee for 12 or nine months, £12; for six months, £8; and for three months, £4. Two resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, and a special dental department. The hospital contains a fully equipped Pathological Department, and a large and extensive X ray Department has recently been added.

Mercy Hospital.—Clinical hospital recognised by the General Nursing Council for Ireland. This hospital contains 130 beds for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical and surgical, also eye, ear, and throat attendances for 1923, 31.952; intern patients, 1499. Daily average, 216·6. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor. Special apartments for nurses and nuns under training. Large children's ward cannot be worked for want of funds.

Cork Mental Hospital (Psychological Medicine).—A course of Clinical Lectures on Mental Diseases and Allied Neuroses will be delivered by the Resident Medical Superintendent in the Cork Mental Hospital as soon as possible after the opening of the Trinity Term. The lectures will comprise: Normal Psychology; Psychology of the Insane; Psychoses, Statistics, Classification. Ætiology, Symptomatology, Diagnosis, Prognosis, Pathology and Treatment, Psychoneuroses; Neuroses. The course will be illustrated by typical cases of the various forms of Mental Affections. For further particulars apply to Dr. Owen F. McCarthy, Resident Medical Superintendent.

Victoria Hospital (Incorporated) (Cork).—There are 75 beds. Clinical instruction on Diseases Peculiar to Children is given. The extern department is open daily at 9.30.

County and City of Cork Lying-in Hospital (Erinville, Western-road; founded 1798).*—This hospital contains 22 beds, an Extern Midwifery Department, Gynæcological Department, Extern Department for Women, and Child Welfare Centre. Training Centre for Midwives, preparing for C.M.B. examinations. Fee for six months' attendance, including clinical lectures, £5 5*s.* For further particulars apply to Lucy E. Smith, M.D., secretary to staff.

Cork Maternity (Batchelor's Quay).*—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes and there are 8 intern beds. A Child Welfare Centre and Clinic was established in 1919. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate, £5 5*s.* Honorary secretary to staff, Dr. Henry Corby.

*Cork Fever Hospital.**—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

Cork District Hospital (Douglas-road; 1200 beds).—This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynæcology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. D. Morrissy, 88, South Mall, Cork, honorary secretary, medical staff.

Cork Eye, Ear, and Throat Hospital (Western-road).*—This hospital is open to students attending the

---

* No returns.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital or other recognised institution, a six months' course in Trinity College, and then pass a special examination. Three months of each of the courses may be taken concurrently.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Clinical Instruction.—The hospital facilities for clinical instruction available in Dublin will be described below.

NATIONAL UNIVERSITY OF IRELAND.*

Matriculation.—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres. All students must pass in five subjects (three of which must be Irish, English, and mathematics). All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other modern language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate, History and Geography (*as a composite subject*), Natural Philosophy, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology and Hygiene. Candidates who under the regulations are exempted from the necessity of presenting Irish as one of their subjects, may present as their fifth subject either a second language or a second science subject. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, may be accepted as matriculated students of the Faculty of Medicine on passing the matriculation examination in any faculty of the University.

The medical degrees granted are:—

M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908. Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College. The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and coöpted lecturers, a body of graduate members, and a body of student members matriculated in the University. The first professors and lecturers were appointed by the Dublin Commissioners Irish Universities Act, 1908.

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland.

Universities Examinations in Medicine.—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and Materia Medica.

Degrees of M.B., B.Ch., and B.A.O.—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year when the curriculum has been completed. The course of study is as follows:—First year.—Winter: Anatomy and Practical Anatomy (required for the Second Examination), Applied Chemistry, Materia Medica and Pharmacology, Applied Anatomy and Physiology, Practical and Applied Physics (with Laboratory Course). Summer: In addition, Applied Biology, Anatomy, and Physiology. Second Year.—Winter: Anatomy, Practical Anatomy, Physiology, and Practical Physiology (physical and chemical). Summer: Anatomy, Practical Anatomy, Physiology, and Practical Histology. Third year.—Winter: Pathology, Surgery, Materia Medica and Pharmacology, Applied Anatomy and Physiology, and Pharmacy. Summer: Materia Medica and Therapeutics, and Practical Pathology. Candidates are also required to attend a General Hospital for nine months (winter and summer). Fourth year, or fourth and fifth years.—Medicine, Medical Jurisprudence and Hygiene, Midwifery and Gynæcology, Operative Surgery, Therapeutics, Applied Anatomy, and Ophthalmology and Otology. Candidates are also required to attend a General Hospital for nine months (winter and summer), and to take instruction in Vaccination, and three months Fever Hospital. Fifth year.—If the Academic (Collegiate) Courses are taken as above, the Courses of the fifth year will be the following: Hospital Attendance, General Hospital, nine months; Clinical Ophthalmology and Otology, three months; Practical Midwifery and Gynæcology, six months; Mental Diseases, to be attended at a Lunatic Asylum, three months. (*Note.*—Practical Midwifery and Gynæcology may be taken in the fourth year after the Systematic Course of Midwifery, but it must not be taken concurrently with the period of attendance at Fever Hospital.) Hospital attendance on Diseases of the Skin, Children's Diseases, Diseases of the Ear, Throat and Nose, Venereal Diseases, and instruction in Radiology are also included in the new curriculum. The degree of M.D. may be obtained either by examination or on published work.

Fees.—The fees for Courses may be obtained on application to the Registrar for the College publications.

Information concerning these, and the numerous scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Prof. E. P. McLoughlin.

UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting once in each year in the Mardyke grounds.

---

* No returns.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who are candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council. For information as to the conditions and courses of the Matriculation Examination application may be made to the Registrar, National University, Dublin.

Admission of Medical Students.—Students who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may be admitted to the rank of fourth-year students.

Residence of Students.—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, the Cork Fever Hospital, the Cork District Hospital, and the Cork Ear, Eye, and Throat Hospital.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, Professor A. E. Moore.

*South Charitable Infirmary and County of Cork General Hospital** (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for nine months, £12 12*s.*; for six months, £8 8*s.*; for three months, £4 4*s.* Two resident pupils will be appointed by competitive examination.

Cork North Charitable Infirmary and County and City of Cork General Hospital (112 beds).—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior students on two days weekly. Fee for 12 or nine months, £12; for six months, £8; and for three months, £4. Two resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, and a special dental department. The hospital contains a fully equipped Pathological Department, and a large and extensive X ray Department has recently been added.

Mercy Hospital.—Clinical hospital recognised by the General Nursing Council for Ireland. This hospital contains 130 beds for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical and surgical, also eye, ear, and throat attendances for 1923, 31,952; intern patients, 1499. Daily average, 216·6. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor. Special apartments for nurses and nuns under training. Large children's ward cannot be worked for want of funds.

Cork Mental Hospital (Psychological Medicine).—A course of Clinical Lectures on Mental Diseases and Allied Neuroses will be delivered by the Resident Medical Superintendent in the Cork Mental Hospital as soon as possible after the opening of the Trinity Term. The lectures will comprise: Normal Psychology; Psychology of the Insane; Psychoses, Statistics, Classification, Ætiology, Symptomatology, Diagnosis, Prognosis, Pathology and Treatment, Psychoneuroses; Neuroses. The course will be illustrated by typical cases of the various forms of Mental Affections. For further particulars apply to Dr. Owen F. McCarthy, Resident Medical Superintendent.

Victoria Hospital (*Incorporated*) (Cork).—There are 75 beds. Clinical instruction on Diseases Peculiar to Children is given. The extern department is open daily at 9.30.

County and City of Cork Lying-in Hospital (Erinville, Western-road; founded 1798).*—This hospital contains 22 beds, an Extern Midwifery Department, Gynæcological Department, Extern Department for Women, and Child Welfare Centre. Training Centre for Midwives, preparing for C.M.B. examinations. Fee for six months' attendance, including clinical lectures, £5 5*s.* For further particulars apply to Lucy E. Smith, M.D., secretary to staff.

Cork Maternity (Batchelor's Quay).*—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes and there are 8 intern beds. A Child Welfare Centre and Clinic was established in 1919. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate, £5 5*s.* Honorary secretary to staff, Dr. Henry Corby.

*Cork Fever Hospital.**—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

Cork District Hospital (Douglas-road; 1200 beds).—This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynæcology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. D. Morrissy, 88, South Mall, Cork, honorary secretary, medical staff.

Cork Eye, Ear, and Throat Hospital (Western-road).*—This hospital is open to students attending the

---

* No returns.

University College and others. Certificates of attendance for three or six months can be obtained. The hospital contains 35 beds. Over 3000 cases are treated during the year. A course of lectures is delivered during the session; also a post-graduate course of instruction. For further information apply to Dr. Arthur Sandford, Eye, Ear and Throat Hospital.

University College, Galway: School of Medicine.—The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £20 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value £20 each, are reserved for Medical Students. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Hospital and in the Galway Union and Fever Hospitals, containing on an average 200 patients.

*Galway Union and Fever Hospitals** (150 beds).—Clinical instruction is given in these hospitals to the Medical Students of University College, Galway. The regulations for Scholarships tenable in the College, and the regulations for degrees and for courses can be obtained from Messrs. O'Gorman and Co., Galway.

Central Hospital, Galway, Prospect Hill Branch (62 beds).—Founded by Act of Parliament.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations known as the First, Second, Third, and Fourth Medical Examinations respectively.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject thereof.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory. —In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical Instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum.

Royal Victoria Hospital, Belfast (350 beds).—Students eligible for McGrath, McQuitty, Malcolm, and Coulter Scholarships aggregate annual value £170. Ten House Surgeons and House Physicians. 36 resident pupilships, three months each, annually for Senior Students, of which a proportion is allotted to Women Students. Special Departments for Radiology, Clinical Pathology, V.D., Dermatology, Gynæcology, Vaccine Therapy, Electro-cardiography, Dentistry.

Mater Infirmorum Hospital (220 beds).

Belfast Infirmary and Hospital (1600 beds).—Clinical courses are given biennially, and a course for D.P.H. in Hospital. Intern Venereal Clinic in Infirmary under Corporation scheme. Maternity Hospital recognised for Practical Midwifery training. Particulars may be obtained on application, as to classes, to Dr. McLiesh. Certificate of vaccination class recognised by Local Government Board. A new department for Cancer with 32 beds has been opened.

Belfast Hospital for Sick Children, Queen-street.—Clinical instruction is given in this hospital. During the Winter Session two Courses of Lectures are delivered on the Medical and Surgical Diseases incidental to Infancy and Childhood. Demonstrations in Ophthalmology and Pathology are given, and ample opportunities are afforded in the wards (which contain 45 beds), and in the Out-patient Department, which is largely attended, for gaining a practical and theoretical knowledge of the diseases of Infancy and Childhood. This Hospital grants Certificates in Diseases of Children, which are recognised by the various Examining Bodies. A Gold Medal is offered for competition at the close of the session. Fee for the session—2 guineas. For re-attendance—1 guinea. Hon. Secretary to the Medical Staff, Dr. Rowland Hill

Maternity Hospital, Townsend-street, Belfast.*—25 beds in constant occupation, and exclusively devoted to Midwifery and Ante-natal conditions. There is also a large district. Students are welcomed, and clinical lectures are delivered daily by a member of the Staff. There is also a large Ante-Natal Department where clinical instruction is given twice weekly. The Hon. Secretary of the Medical Staff is H. L. Hardy Greer, F.R.C.S.

Ulster Hospital for Children and Women, Templemore-avenue, Belfast (52 beds).—Clinical instruction to students in Diseases of Children, Gynæcology, and Obstetrics. Special departments: Radiology and Eye, Ear, and Throat. Gold Medal awarded annually. One House Surgeon appointed from students of hospital.

Benn Ulster Eye, Ear and Throat Hospital, Incorporated, Clifton-street, Belfast (30 beds).

Belfast Ophthalmic Hospital, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and Laryngology. Clinical instruction is given daily.

Belfast Fever Hospitals.—City Fever Hospital, Purdysburn (330 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-Graduate (D.P.H.) Classes are also held. Lecturer: A. Gardner Robb, M.B., D.P.H.

Belfast Mental Hospital (*Purdysburn Villa Colony*) (1000 beds).

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15*s.* to non-Licentiates.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

---

* No return.

University College and others. Certificates of attendance for three or six months can be obtained. The hospital contains 35 beds. Over 3000 cases are treated during the year. A course of lectures is delivered during the session; also a post-graduate course of instruction. For further information apply to Dr. Arthur Sandford, Eye, Ear and Throat Hospital.

University College, Galway: School of Medicine.—The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £20 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value £20 each, are reserved for Medical Students. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Hospital and in the Galway Union and Fever Hospitals, containing on an average 200 patients.

*Galway Union and Fever Hospitals** (150 beds).—Clinical instruction is given in these hospitals to the Medical Students of University College, Galway. The regulations for Scholarships tenable in the College, and the regulations for degrees and for courses can be obtained from Messrs. O'Gorman and Co., Galway.

Central Hospital, Galway, Prospect Hill Branch (62 beds).—Founded by Act of Parliament.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations known as the First, Second, Third, and Fourth Medical Examinations respectively.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject thereof.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory. —In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15s. to non-Licentiates.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

---

* No returns.

Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars as to fees and conditions of examination can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

Professional Examinations.—There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognised medical schools at home and abroad. The first examination deals with (*a*) Anatomy, and (*b*) Physiology and Histology. The second examination deals with (*a*) Pathology, (*b*) Materia Medica, Pharmacy, and Therapeutics and Ophthalmology, and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (*a*) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (*b*) Surgery, including Operative Surgery; (*c*) Midwifery, including Diseases of Women and Newborn Children, and the Theory and Practice of Vaccination.

Fees.—Preliminary Examination, £2 2*s.*; Re-examination, £2 2*s.* Pre-Registration Examination, £3 3*s.* Re-examination in Chemistry, £2 2*s*; in Physics, £1 1*s.* First Professional Examination, £15 15*s.*; Second, £15 15*s.*; Final, £6 6*s.* Re-examination fee is £2 2*s.* for each division.

Diploma in Psychological Medicine.—There are two examinations in connexion with this Diploma: Part I. consists of (*a*) Anatomy and Physiology of the Nervous System; (*b*) Psychology. Part II.: (*a*) Neurology, including Clinical and Pathological Neurology; (*b*) Psychological Medicine, including its legal relationships.

Fees.—£3 3*s.* for each part.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5*s.*; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.*

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are three professional examinations, the total fees for which amount to £26 5*s.* 6*d.* Women are eligible for the diploma.

There are four examinations—primary, intermediate, Parts I. and II., and final. They are held three times a year, in March, June and December. The primary examination comprises biology, physics, theoretical and practical chemistry (with an examination at the bench). Candidates holding a Pharmaceutical licence are exempt from this subject. Intermediate, Part I., Anatomy and Physiology. Intermediate, Part II., Pathology, Medical Jurisprudence, and Materia Medica and Pharmacy. The intermediate examination comprises anatomy of the whole body (including practical dissections), physiology, practical histology, and materia medica. The final examination comprises medicine, surgery, and midwifery.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 95, Merrion-square, Dublin.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.[1]

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.*—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Ten Resident Pupils are appointed every four months. Six surgical Dressers and six Clinical Clerks are appointed each month. There are facilities for women students.

Prizes and Medals.—Clinical medals and prizes amounting to about £21 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

---

* No returns.

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in some of the Irish centres have been described.

Fees.—Winter and summer session, £12 12*s.*; winter session (six months), £8 8*s.*; and summer session (three months), £5 5*s.* Special certificate in anæsthetics, £1 1*s.* The practice of this hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

The Hospital is an official "Treatment Centre" for venereal diseases.

Further information will be supplied by the Hon. Secretary to the Medical Board.

Coombe Lying-in Hospital and Guinness Dispensary for the Treatment of Diseases Peculiar to Women, Dublin.—This hospital contains 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. There is accommodation for intern pupils who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. The residents' quarters are comfortable. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Fees: Extern pupils for full course of six months, £8 8*s.*; three months, £4 4*s.* Intern pupils, one month, £4 4*s.*; each consecutive month, £3 3*s.*; six months, £18 18*s.* Registration fee, in advance, 10*s.* 6*d.* Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the Hospital.

Adelaide Hospital, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s.*; six months, £8 8*s.* Summer, three months, £5 5*s.*[1] Two resident surgeons are elected half-yearly and four or more resident pupils every four months. At the termination of the session prizes in Clinical Medicine, in Surgery, in Gynæcology, and in Dermatology will be awarded.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Dr. L. G. Gunn.

Jervis-street Hospital, Dublin.—Founded 1718; rebuilt 1886. 130 beds. A new operation theatre (1923) has been completed and contains all modern requirements.

Mater Misericordiæ Hospital, Dublin. (Under the care of the Sisters of Mercy.)—This Hospital was founded in 1861 by the Sisters of Mercy. It is the largest in Ireland, containing 382 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical operations will be performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents; a fully-equipped Biochemical Laboratory, a modern Electro-Massage Department, and Electro-cardiograph room. Instruction will be given on Pathology and Bacteriology. Three House Physicians, eight House Surgeons, and 27 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases; also a Training School and a Home for Trained Nurses in connexion with the Hospital. Trained and experienced Nurses who have passed a qualifying examination in nursing can be obtained on application to the Lady Superior, Mater Misericordiæ Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. John O'Donnell, 3, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Medical Board, Mr. H. Barniville, 9, Merrion-square.

Meath Hospital and County Dublin Infirmary. This hospital was founded in 1753 and now contains 150 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical Clinical Clerks and Surgical Resident Pupils and Dressers are appointed every three months, and House Surgeons and Clinical Assistants are elected annually. Apply to Hon. Secretary and Treasurer of the Medical Board.

Mercer's Hospital.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients and a modern X ray department. An electro-cardiograph has been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from amongst the most deserving members of the class.

Fees.—Winter, six months, £8 8*s.*; Summer, three months, £5 5*s.*; nine months, £12 12*s.*

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square, Dublin.

National Maternity Hospital, Holles-street, Dublin.—Established 1894. The hospital consists of an Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children. About 1035 cases are admitted and over 300 operations are performed annually. Every facility is given for the carrying out of practical work. Post-graduate and special courses are arranged for at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Terms.—Intern Pupils: Six months, 16 guineas; three months, 9 guineas; two months, 6 guineas; one month, 3 guineas. Extern Pupils: Certified Courses (three months), 6 guineas; Post-graduate Courses by special arrangement. Clinical Lectures are given daily and Oral Lectures four times per week. During the past year over 50 Post-graduate students were admitted. The L.M. Diploma is given by special examination on arrangement with the Masters. Further particulars can be obtained from the Masters: Sir Andrew Horne, 94, Merrion-square, Dublin; Dr. Patrick McArdle, 27, Merrion-square; or from the Secretary, Holles-street, Dublin.

---

[1] Special Lectures in Dermatology are given weekly; also practical demonstrations on the treatment of fractures from time to time.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS (HOUSE OF INDUSTRY HOSPITALS), Dublin.*—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 20 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon. Secretary, 69, Fitzwilliam-square, Dublin.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually and 500 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M. and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s*., months other than the first £4 4*s*., three months £12 12*s*., six months £21. For further particulars apply to the Master.

ROYAL CITY OF DUBLIN HOSPITAL.—Founded 1832; enlarged 1851; rebuilt 1893. 130 beds. There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. Secretary: G. R. Shine.

ROYAL VICTORIA EYE AND EAR HOSPITAL, Dublin. —Established 1844. Incorporated 1897. 102 beds. In-patients, 1499; out-patients, 8492. Two house surgeons for Eye and one for Ear appointed annually.

DR. STEEVENS' HOSPITAL, Dublin (Kingsbridge).—Established 1720. 250 beds, only 150 now in use. Patients, intern, 1300; extern dispensary attendances, including special V.D. Clinic, 38,479. There is accommodation for 12 Resident Pupils, each of whom is provided with a separate bedroom, and board is supplied by the Hospital, at a reasonable rate. All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

ST. VINCENT'S HOSPITAL AND DISPENSARY, Dublin.*—Established 1834. 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for Senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Farrell gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the Surgeon McArdle Prize, value £20. In the coming term it is hoped that there will be opened a New Extern Department and a New Pathological Laboratory. Dr. Meenan, hon. secretary, 28, Fitzwilliam-square.

* No returns.

WE take this opportunity of thanking the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

PRISON MEDICAL SERVICE.

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. 1. In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from the seniors of this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £600, making the pay at present with bonus £504 14*s*. to £801 11*s*.; Medical Officer, Class I., £650, rising by annual increments of £25 to £800, plus bonus, making the pay £864 to £1023 9*s*. Unfurnished quarters are provided or an allowance in lieu is made. There are 12 full-time medical officers of Class I. and 14 Class II., and 26 part-time medical officers. The number of vacancies is never large and promotion is slow. In the case of a part-time medical officer, the population of the prison is the basis of fixing the salary, unless there are some special features justifying special consideration. A committee was recently set up to inquire into the emoluments of prison officers, including medical officers, and the pay is in accordance with its recommendations.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 16TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 42; scarlet fever, 1433; diphtheria, 630; enteric fever, 91; pneumonia, 397; puerperal fever, 41; cerebro-spinal fever, 8; acute poliomyelitis, 29; encephalitis lethargica, 70; typhus fever, 2; trench fever, 1; dysentery, 2; ophthalmia neonatorum, 124. No cases of cholera or plague were notified during the week. The cases of typhus were notified from the county borough of St. Helens.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever; none from small-pox; 12 from scarlet fever; 18 from diphtheria; 22 from measles; 15 from influenza. In London itself the diphtheria deaths numbered 6.

THE LANCET.

LONDON: SATURDAY, AUGUST 30, 1924.

MEDICAL TRAINING.

IN a month from now the medical schools of the country will be commencing the new academic year, and at each centre where training is available young men and women who have selected medicine as a vocation will be joining their fellow-students in the march towards qualification. In the earlier issues of THE LANCET, when special supplements were regularly addressed to intending students, stress was often laid upon the advantage to be derived from entering this or that school, but to-day medical education, wherever provided, must follow to a great extent a uniform plan, a fact which is the clearest proof that during the past century progress along definite lines has been made in the methods of preparing for professional life. Look, for example, at two letters published in THE LANCET last week: one which had somehow escaped previous publication, addressed by the great JOHN HUNTER to the surgical staff of St. George's Hospital, and the other, a comment upon the first, written by THOMAS WILLIAMS who was HUNTER'S senior on the staff of the hospital. The two communications display in a striking manner the pattern of medical education in London at the end of the eighteenth century, and it was the pattern of medical training throughout the country. Medical education was conducted on a system of apprenticeship to the hospital generally—"pupils in common"; or, and more frequently, to individual members of the staff—"pupils in particular," the money received from both sources being at the outset divided equally among the staff. The students paid for their education and obtained in return instruction from the staff and the right to "walk the hospital." The personal contact between what were virtually masters and apprentices had sometimes its advantages, though hardly of a scientific sort; but the disadvantages, in the absence of an organised curriculum, were overwhelming, for it was a matter of chance whether an individual member of the staff took his share in the education of the "pupils in common," while the "pupils in particular" were the objects of a nepotism whose abuses need not be enlarged upon.

That was the condition at the end of the eighteenth century, but our medical students are now trained upon a definite system and with definite objects in view. The system has been slowly evolved and is not a perfect one; nor will it ever reach perfection we are glad to know, for it must always follow on the progress of our science. Systematic training in scientific medicine and surgery was a sequel, but not an immediate sequel, to the work of JOHN HUNTER, and while that great man was himself a hospital officer the curriculum of the student was as fortuitous as can be imagined. The briefest study of this issue of THE LANCET, which is written as a guide to medical education, will show how elaborate the scheme of training is to-day, though it is not more elaborate than might be expected in a curriculum which has been sifted and modified, simplified and amplified as new knowledge has brought new needs. It may be that the simplification is not so obvious as the amplification, for the complaints that the curriculum is overloaded remain general, although we hear at least as frequently the complaints of those who find that adequate instruction is not given along certain lines—obstetrics, ophthalmology, and mental disease, for example, being subjects in which practical equipment has been found wanting. All this is testimony to the fact that medical education is a living affair, conforming to the rules of life, under which the old is perpetually replaced by the new, and purposeful movements are found as the outcome of apparently disconnected facts. Medicine is experiencing at the moment acute phases of this development, and thus the educational course of the student becomes an extremely difficult one: long in time, it requires industry and self-restraint in the worker lest it should become far longer than it is designed by the regulations to be; and complicated in pattern it asks from him a pertinacity that has to be clear-headed as well as unrelaxing. We can well understand the parent looking at what lies before the intending student and asking: Do you really want to be a doctor? And if such a parent inquires further, the following is all the comfort that we can give him, while saying, at the same time, that to the man who knows his own heart, medicine has the finest reward to offer.

The opportunities for practice abroad are increasing, if international reciprocity is still far away, as will be gathered from an annotation on the next page. A graph appears there also which indicates that the profession will be no longer overcrowded, though the drop in the registrations must be interpreted in accordance with the new regulations for study. But the outlook in medicine as a profession has never been more doubtful than it is at the present moment. On all sides changing conditions produce anxiety as to what the future will bring forth. The report of the Lee Committee has so altered the outlook for the Indian Medical Service that many doubt if there is any outlook at all. The stated policy of certain members of the Government now in power, pledging themselves to the principle of State Medical Service, depresses those whose belief is whole-hearted in the individualistic ideals of medical practice. Local sanitary and educational authorities are practising economies in the payment of their medical staffs which are only rendered possible by the economic position of the medical applicants. And on all those who enter private practice rests the fear that they may be mulcted in huge damages for statements made in all good faith, or for measures which have not turned out to the satisfaction of the patient. Those who do not possess a large supply of courage, of industry, and of that quality of moving with the times which is closely related to the spirit of adventure, may be disappointed with their choice of a calling if they join our ranks. But medicine is not a static thing unable to move with social and political development, and, to many of those who look forward to entering it, the dynamic aspect is an attraction. Opportunities are opening before the coming generation which were quite undreamed of by the generation which is passing, and, to all those who possess the qualities, the outlook may certainly be doubtful but will be none the worse for that. Thus there is one answer to the question, "Do you really want to be a doctor?" which will always prevail, and that is an affirmative which depends upon an inward conviction that there is no finer form of service by man to man. Profoundly as medicine has changed since the days of SYDENHAM, LATHAM, and BRIGHT, the ideals set out by those great men (see p. 480) remain constant.

are arranged for at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Terms.—Intern Pupils: Six months, 16 guineas; three months, 9 guineas; two months, 6 guineas; one month, 3 guineas. Extern Pupils: Certified Courses (three months), 6 guineas; Post-graduate Courses by special arrangement. Clinical Lectures are given daily and Oral Lectures four times per week. During the past year over 50 Post-graduate students were admitted. The L.M. Diploma is given by special examination on arrangement with the Masters. Further particulars can be obtained from the Masters: Sir Andrew Horne, 94, Merrion-square, Dublin; Dr. Patrick McArdle, 27, Merrion-square; or from the Secretary, Holles-street, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS (HOUSE OF INDUSTRY HOSPITALS), Dublin.*—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 20 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. PRISON MEDICAL SERVICE.

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. 1. In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from the seniors of this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £600, making the pay at present with bonus £504 14*s*. to £801 11*s*.; Medical Officer, Class I., £650, rising by annual increments of £25 to £800, plus bonus, making the pay £861 to £1023 9*s*. Unfurnished quarters are provided or an allowance in lieu is made. There are 12 full-time medical officers of Class I. and 14 Class II., and 26 part-time medical officers. The number of vacancies is never large and promotion is slow. In the case of a part-time medical officer, the population of the prison is the basis of fixing the salary, unless there are some special features justifying special consideration. A committee was recently set up to inquire into the emoluments of prison officers, including medical officers, and the pay is in accordance with its recommendations.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 16TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 12; scarlet fever, 1433; diphtheria, 630; enteric fever, 91; pneumonia, 397; puerperal fever, 41; cerebro-spinal fever, 8; acute poliomyelitis, 29; encephalitis lethargica, 70; typhus fever, 2; trench fever, 1; dysentery, 2; ophthalmia neonatorum, 124. No cases of cholera or plague were notified during the week. The cases of typhus were notified from the county borough of St. Helens.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever; none from small-pox; 12 from scarlet fever; 18 from diphtheria; 22 from measles; 15 from influenza. In London itself the diphtheria deaths numbered 6.

NAVAL MEDICAL SERVICE.

The life offered to officers of the Royal Naval Medical Service is one that ought to appeal to a large section of recently qualified medical men. There is no intention in what follows, under this or the subsequent headings, to pit one Service against the other or to recruit in one direction more than in another. The particular regulations for each Service should suffice to give each man the necessary impetus for a decision, but it is useless to disguise the fact that the attitude of the authorities in respect to the compulsory retirement at the age of 50 of a group of surgeon commanders who were under contract to be employed until the age of 55 has produced an unfortunate impression. It creates a difficulty for those who are in a position to advise young men as to their future careers when they give counsel based upon engagements which may later be repudiated. The situation has evoked a formal protest from the British Medical Association, and although no specific action was recommended to the Association by its Representative Body, certain protests have found their way into the public press and cannot have failed to prejudice recruiting for the service.

A conference consisting of representatives of the Admiralty and the Medical Department of the Admiralty, and the Services Committee of the British Medical Association was held on Jan. 29th, 1924. A report of this meeting was published in the *British Medical Journal* Supplement of Feb. 16th, 1924. The whole matter of the conditions of the Naval Medical Service is now under consideration by the Board of Admiralty, particularly that of the position of the surgeon-commanders who were compulsorily retired under the new age regulation. It is hoped that the present deliberations will result in the future conditions and status of the Naval Medical Service being placed on a sound working basis satisfactory to all concerned.

In the Navy the young medical officer sees the world in congenial company and with an assured position, the pay is good, the pensions are commensurate, and the opportunities offered now for scientific work are real, while, if they are taken, promotion awaits the officer on grounds of professional merit.

Rank of Surgeon Lieutenant-Commander will be granted to surgeons at the expiration of six years from date of entry, and the point upon which stress should be laid is that special promotion can be made in cases of conspicuous professional merit, which is thus placed on a par with general service. Six years later the period of promotion to Surgeon Commander is reached, after the qualifying examination has been passed, when again special promotions can be made for conspicuous professional merit as well as for distinguished service; but promotions are limited in number, save, of course, for gallantry in action. This recognition of professional attainment should prove a very real incentive to progressive scientific work. The same principle prevails in the higher ranks. Promotions to Surgeon Captain and later to Surgeon Rear-Admiral are made strictly by selection, but are confined to officers who prove fitted, both professionally and as administrators, for this rank.

Naval life may lead to opportunities for putting into practice much of what has been learned in the clinical wards of a hospital. Further, the opening for preventive medicine is large and many-sided, while appointments to the large shore establishments enable medical officers to keep their work modern.

New chemical explosives, as well as the extraordinary behaviour of common articles under extraordinary conditions of stowage, furnish perpetual problems and surprises for the medical officer on board ship, and bring him into intimate connexion with his charges in a way that is particularly necessary considering the conditions of life. No medical officer can expect to succeed unless he secures the confidence of those committed to his charge, and the health lectures which he is bound to deliver will be much more fruitful if they are delivered to an audience which trusts him. Moreover, the delivery of official lectures does not end this side of the medical officer's duties. He must be ready to answer questions, sometimes of real acuteness, which are put to him by the modern blue-jacket, and he will find that his lectures will often afford a starting point of work that may develop into great professional interest. Thus, without his being necessarily a psychologist, his influence will be felt by both officers and men, until the well-being of the ship may be profoundly affected by the extent of his tact and skill; for example, small matters assume undue proportion under stress of confinement, and the medical officer should be quick to detect danger signs and warn his commanding officer. Numerous changes have been introduced during the last 20 years into the naval dietary, many of which were the outcome of representations and research by naval medical officers. The work wants carrying on, for much of it has gone to show that the food problem is very complicated. Every medical officer on board ship should make himself acquainted with food values and the human powers of assimilation under varying conditions of work and climate, and here there is ample scope for research. The modern requirements of gunnery and navigation necessitate precision in their use and have made ophthalmology a valuable subject for study in the Navy. The physical training of both officers and men is based on physiological axioms which are peculiarly the field of the medical officer; this training should be the subject of a watchful eye. There is no lack of scope here for professional work without making any reference to the vast problems which have to be faced when the medical officer has to arrange his particular department to the best advantage during or after an action. It is certain that he will not be able to do this unless in times of peace he gets himself ready by study. Lastly, there is the whole field of venereal and tropical disease.

The young medical officer need not be afraid that his work will be without scientific interest if he takes the opportunities offered him.

Conditions of Service.

The rates of pay of the Medical Service are subject to periodical revision in the light of the cost of living, and it is necessary to indicate as closely as practicable the extent and methods of the periodical revision.

In order that students may be under no misapprehension regarding their remuneration should they decide to join the Naval Medical Service, it should be clearly understood that when the pay of naval officers was revised in 1919 it was definitely laid down that 20 per cent. of the rates of full pay, unemployed pay, half pay, and retired pay was to be considered as due to the high cost of living in 1919, and that it should be subject to change periodically either upwards or downwards according as the cost of living rose or fell. The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent., and further revisions (not necessarily reductions) are due every three years—i.e., in July, 1927, July, 1930, and so on.

The pay of the Naval Medical Service is shown in two tables, one showing the scale introduced in 1919, which is described as the standard rates and of which 20 per cent. is variable, and the other showing the actual scale in force from July 1st, 1924, to June 30th, 1927.

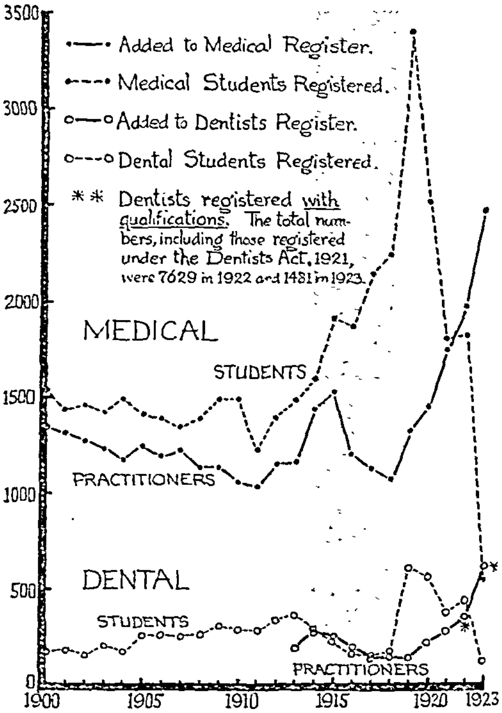
For the time being the regulations for entry by examination into the permanent service are in abeyance, but a short-service scheme providing for transfer to the permanent service has been inaugurated. The regulations for the entry of surgeon lieutenants under this scheme provide for the usual qualifications of registration, good character, physical fitness, and age—the age not to exceed 30 years. The conditions of service are a three years' engagement with an

Annotations.

"Ne quid nimis."

THE PORTAL OF MEDICINE.

A rough idea of the numbers entering the medical profession, both as students and practitioners, may be gained from a study of the accompanying graph, based upon the figures given in the last issues of the Medical and Dental Registers. It should, however, be borne in mind that the number of medical students who were registered last year by the General Medical Council is not a precise indication of those who actually entered upon the curriculum. A certain number of students who would, under the old regulations, have begun the study of chemistry and physics in October, only began their pre-registration work at this time, and instead of being registered in that month will probably register some time this year. It appears, further, that the northern universities are not making arrangements to bring the new curriculum into force until the current year. Consequently students who commence study there are not at present registered. There is no doubt, however, that after these corrections have been applied there will remain a considerable drop in numbers, although it will not be so large as is indicated by the graph when 1923 and 1924 are reviewed together. By reason of the revised curriculum the year 1923 was in some degree an interregnum.



The stippled band represents the period of hostilities, 1914–1918.

PRACTICE ABROAD.

In an annotation which appeared in The Lancet last week, it was pointed out that anyone who has obtained a medical diploma entitling him to have his name printed in any section of the Medical Register becomes at once entitled to practise with little further formality over the greater part of the globe. The range includes, outside the United Kingdom, all the British Dominions and Crown Colonies, with the single exception of British Columbia. He will only require to present the prescribed evidence of the possession of degree or diploma of registration, and, if asked for, of good character, to the proper authorities in Australia, Canada, Ceylon, Hong-Kong, India, Malta, Newfoundland, New Zealand, the Union of South Africa, and the Straits Settlements, in order to enjoy the full privileges and responsibilities of medical practice. In British Columbia those registered prior to 1887 are so entitled; others must pass an examination before a local board, oral and written, in the final professional subjects. Two countries with which there is at present full medical reciprocity are, along with their colonies, also open to all who are on the British Register. These are Japan and Italy. Belgium was in the same category from 1915 to 1920, when a number of Brussels, Louvain, Ghent, and Liége graduates registered in this country, but in the latter year the Belgian authorities saw fit to discontinue the arrangement, and at the same time the Brussels practitioners' degree, an entirely different affair, was discontinued. There is no let or hindrance to record in the reciprocity with Japan; it has apparently worked harmoniously since it was instituted in 1905. But in Italy a temporary difficulty has arisen. Reciprocity was first established in 1901 when practitioners with Italian qualifications became entitled to all the privileges pertaining to British practitioners, but the latter were admitted only to practise amongst foreigners in Italy. In 1910, however, reciprocity became complete, and British practitioners began to enjoy unrestricted freedom of practice in Italy. Last November a registered British medical practitioner, desiring to practise at Ospedaletti, and with the knowledge of the Italian Consul-General in London, was refused permission to do so by the President of the Provincial Medical Board at San Remo, who informed him that he must first obtain an Italian medical diploma. It appears that the provincial authorities had not been apprised of the special agreement between the two countries, and that the matter is likely to be arranged, although those desirous of settling in Italy should bear these facts in mind.

In regard to practice in foreign countries where reciprocity is not in force, the circumstances vary in every possible degree. In China and Siam, for example, there are no regulations whatever restricting practice, whereas in pre-war Austria it was necessary to become naturalised before practice could be begun. In countries nearer home the regulations in France and Switzerland are of special interest; in both procedure has tended to stiffen of recent years. In France it is now necessary to obtain the baccalauréat and to go through the course of study culminating in a medical degree just as any French student would have to do. There is no privilege accorded to medical diplomates as such. In Switzerland it is now obligatory to pass all three professional examinations, as well as the matriculation examination, in the right order; but there is still apparently no obligation to attend courses of study other than are necessary to pass the examinations. In the case of Switzerland there is no reason to believe that the protective measures have been framed in any way with regard to this country: in a land so largely populated by permanent or temporary visitors from adjacent countries of similar speech some such action may be required if it is desired to retain medical practice in the hands of the Swiss themselves. Probably the temporary difficulty in Italy was of the same nature. Negotiations in regard to reciprocity with Spain have made no progress.

Dr. Algernon D. Brenchley has been elected Master of the Society of Apothecaries of London.

London Water.—The eighteenth annual report on the Chemical and Bacteriological Conditions of the London Water-supply has reached us. Written by Sir Alexander Houston, Director of Water Examination, Metropolitan Water Board, it deals with problems of chlorination and filtration, discusses the taste of chlorinated waters, and refers to the various sources of possible contamination. A section is devoted to "medicated" waters, and the repugnance of consumers to the addition of any chemicals to their water-supply is sympathetically noticed.

to hold an appointment as Dental Officer in a recognised Civil Hospital. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list. It is also proposed to allow a three months' Post-graduate Course to Surgeon Lieutenant Commanders (D) of over two years' seniority.

As in the case of the medical branch, 20 per cent. of the rates of full pay, unemployed pay, half pay, and retired pay introduced in 1919 is considered as due to the high cost of living in 1919 and subject to change periodically either upwards or downwards according as the cost of living rises or falls. The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent., and further revisions are due every three years—i.e., in July, 1927, July, 1930, and so on. The following table and paragraphs show the standard rates introduced in 1919, of which 20 per cent. is variable and the present rates which will operate from July 1st, 1924, to June 30th, 1927. The rates of full pay are as follows:—

Full Pay.

Rank.	Standard rate.						Rate from July 1st, 1924.					
	Year of 365 days.			One day.			Year of 365 days.			One day.		
	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.
Surg.-Lieut. (D) on entry..	401	10	0	1	2	0	380	4	2	1	0	10
After 3 years	492	15	0	1	7	0	465	7	6	1	5	6
Surg. Lieut.-Comdr. (D) on promotion	593	2	6	1	12	6	559	13	4	1	10	8
After 3 years	629	12	6	1	14	6	596	3	4	1	12	8
" 6 "	666	2	6	1	16	6	629	12	6	1	14	6
" 9 "	730	0	0	2	0	0	690	9	2	1	17	10
Surg.-Comdr. (D) on promotion	775	12	6	2	2	6	733	0	10	2	0	2
After 3 years	848	12	6	2	6	6	803	0	0	2	4	0
" 6 "	921	12	6	2	10	6	869	18	4	2	7	8
" 9 "	994	12	6	2	14	6	939	17	6	2	11	6

On first appointment to the Service, Dental Officers will receive full pay from the date of appointment, but subject to the provisions of Article 1347 of the King's Regulations, 1913.

Dental Officers are eligible for the same rates of lodging and provision allowances as other officers of equivalent rank and are entitled to the same privileges. The rates of half-pay are:—

Unemployed Pay and Half Pay.—A distinction is to be drawn between—

(*a*) Officers awaiting employment.

(*b*) Those who are permitted for private reasons which the Admiralty regard as satisfactory to refuse an appointment or to have their appointment cancelled or who are unemployed at their own request or in consequence of misconduct.

In the former case—

(*a*) Officers are to receive unemployed pay as follows:—

For the first six calendar months full pay of rank (without allowances).

For the next six calendar months:—

Rank.	Standard rate per diem.			Rate per diem from July 1st, 1924.		
	£	s.	d.	£	s.	d.
Surgeon Lieutenants (D)	0	17	0	0	16	0
Surgeon Lieutenant Commanders (D) ..	1	2	6	1	1	3
Surgeon Commanders (D)	1	7	6	1	6	0

Thereafter:—Half the full pay of their rank and seniority on the Executive Officers' scale, namely:—

Rank.	£	s.	d.	£	s.	d.
Surgeon Lieutenant (D)	0	8	6	0	8	0
" " of 4 years' seniority	0	10	0	0	9	5
Surgeon Lieutenant Commander (D)	0	15	0	0	14	2
" " of 3 years' seniority	0	16	0	0	15	0
" " of 6 years' seniority	0	17	0	0	16	1
Surgeon Commander (D)	1	0	0	0	18	11
" " of 3 years' seniority	1	2	0	1	0	9
" " 6 " "	1	4	0	1	2	8
" " 9 " "	1	6	0	1	4	7

Unemployed pay will not, however, be granted in cases where an officer is undertaking continuous professional work for which payment is made.

In the latter case, (*b*), Officers may receive half the full pay of their rank and seniority on the Executive Officers' scale.

Periods during which unemployed Full Pay or Unemployed Pay are received will only count as half-pay time—that is, as one-third of full service.

An Officer who is permitted, for private reasons, to decline an appointment, or to have his appointment cancelled will not be entitled to any Unemployed Pay. In such cases, Officers may be placed on Half-Pay.

The conditions of retirement, Widows' Pensions, Leave, &c., are the same as for medical officers of equivalent rank and seniority.

Arrangements are also made whereby officers may be allowed to withdraw from the Service after four years' service and receive gratuities on the following scale:—

Gratuities will be awarded on retirement and withdrawal on the undermentioned scale.

Rank.		Gratuity.		
		£	s.	d.
Surgeon Lieutenant (D), Surgeon Lieutenant-Commander (D), and Surgeon Commander (D):				
After 4 years' full-pay service	including service allowed by paragraph 3	500	0	0

ARMY MEDICAL SERVICE.

THE recent alterations in the conditions of service in the Royal Army Medical Corps, which constituted, as we said at the time, the greatest reform that has taken place in that Service for a generation, have well fulfilled their promise. For many reasons which are obvious and have been detailed on previous occasions, the Service can be thoroughly recommended to young medical practitioners. Competitive examinations for commissions into the R.A.M.C. are held twice a year, usually in January and July. The Regulations for admission to the R.A.M.C. should be obtained from the Army Medical Department, War Office, London, S.W. 1, and carefully studied.

These are the things which the man who contemplates joining the Service should bear in mind. The rates of pay and allowances are good; the chances of seeing the world and the opportunities for post-graduate study are generous, and the work is nowadays varied, responsible, and interesting. At certain periods the young officer is relieved from all other duties for five months for the purpose of post-graduate study. During this period he is on full pay and the fees for his courses of instruction are paid by the State. His time is devoted to post-graduate work, and the leading clinical and scientific institutions are coöperating to secure that this post-graduate work shall be real and fruitful. Officers who show a marked aptitude for special subjects and have had previous practical experience in them are now selected to undergo a specialist course lasting for a further four months, thus giving these officers a post-graduate course of nine months. At the same time, in districts where the privilege would be of the most practical value, opportunities are forthcoming for young officers to attend the clinical practice of large local general hospitals.

By a Royal Warrant issued in September, 1919, medical and combatant officers were placed on the same footing as regards retired pay, and the fact that medical officers enter the Service after a long and expensive training some five years later in life than combatant officers was overlooked. This inequality of treatment has now been rectified, with the result that a medical officer of 20 years' service or over gets £70 per annum more pension than a combatant officer with the same number of years' service.

Once again let us deal with the most frequently repeated criticism of the Service—namely, that option of a further year, to serve when and where required under the general rules of the service as regards discipline, and to rank with, but after, surgeon lieutenants in the permanent service, and to receive two calendar months' notice of services being no longer required.

As from July 1st, 1924, the pay is £1 5*s.* (standard rate £1 6*s.* 6*d.*) per day or £456 5*s.* (standard rate £483 12*s.* 6*d.*) per annum, while there is a gratuity, not subject to variation with the cost of living, on discharge of £8 6*s.* 8*d.* for each completed month of service. All officers during service are accommodated and victualled on the usual service scale or receive lodging money and provision allowance in lieu, at rates subject to periodical revision. The present rates of lodging money and provision allowance are £80 and £55 a year respectively. Unlike permanent officers, medical officers entered for short service are not liable to periods of unemployment on unemployed or half pay or eligible for retired pay in respect of service. If, however, such an officer were invalided for a cause certified by the competent naval medical authority as attributable to the conditions of service, he would be eligible for disability retired pay in lieu of the gratuity on discharge referred to above. Similarly, in the event of his death from a cause attributable to the service his widow and children would be treated in the same manner as the widow and children of an officer on the permanent list. There is an equipment allowance for ordinary uniform of £50, but the officer provides himself with a pocket case of instruments and a stethoscope.

A short-service surgeon lieutenant after six months' service, on application to the Secretary of the Admiralty, may be considered for transfer to the permanent service on a satisfactory report being received from the senior medical officer of the Squadron, Hospital or Depôt in which he has served or is serving as to his professional ability, and a favourable report from his commanding officer as to conduct. Such candidates must have been under the age of 28 on joining for short service, and officers so transferred will not be eligible for the gratuities provided. They will be permitted to count their seniority from date of entry for short service for purposes of promotion and for increment of full pay, and similarly they will be permitted to count their service from the date of entry for purposes of retired pay, but for purposes of retiring gratuity on the permanent officers' scale their services will be reckoned only from the date of transfer to the permanent list, this date being that of receipt in the ship or establishment in which the officer is serving of the order for his transfer to the permanent list. Until that date he will retain his temporary rate of pay.

If a short-service lieutenant transfers to the permanent service he will then come under the following conditions of pay and pensions :—

Standard and Present Rates of Pay.

Rank.	Standard rate.						Rate from July 1st, 1924.					
	Year of 365 days.			One day.			Year of 365 days.			One day.		
	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*

Surg. Rear-Admiral ..	1916	5	0	5	5	0	1809	15	10	4	19	2

On first appointment to the service, medical officers will receive full pay from date of appointment, but subject to the provisions of Article 1347 of the King's Regulations.

Officers of the permanent service are eligible during periods of unemployment for unemployed pay and half pay. The rates of unemployed pay and half pay, and the conditions under which they are granted, are the same as in the dental branch and are set forth in detail later in this article.

Flag Allowances.

An allowance of 5*s.* a day in addition to full pay is granted to the Senior Medical Officer of a flagship bearing the flag of a Commander-in-Chief. An allowance of 2*s.* 6*d.* a day is granted to the Senior Medical Officer of a ship bearing other flags or broad pendants.

Standard Rates of Retired Pay.

Compulsory retirement will be as follows :—

(i) Surgeon Rear-Admirals retire at the age of 60 with retired pay at the rate of £900 per annum plus £22 per annum for each year's service over 27 years counting for retired pay, subject to a maximum rate of £1010 per annum. If, however, less than 27 years' service counting towards retired pay is rendered, a deduction of £22 per annum is made for each full year wanting to complete that period, subject to a minimum of £790 per annum.

(ii) Surgeon Captains retire at the age of 55. Maximum retired pay, £900.

(iii) Surgeon Commanders retire at the age of 50. Maximum retired pay, £600.

(iv) Surgeon Lieutenant-Commanders and Lieutenants retire at the age of 45. Maximum retired pay, £450.

Subject to these maxima, the rates of retired pay for Surgeon Captains, Surgeon Commanders, Surgeon Lieutenant-Commanders, and Surgeon Lieutenants are as follows :—

Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)		Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)	
			Addition.	Deduction.				Addition.	Deduction.
	£ (p.a.)		£ (p.a.)	£ (p.a.)		£ (p.a.)		£ (p.a.)	£ (p.a.)
55	790	24	22	15	47	562	20	15	15
54	765	24	22	15	46	525	20	15	15
53	742	23	22	15	45	487	19	15	15
52	720	23	22	15	44	450	19	15	15
51	697	22	22	15	43	412	18	15	15
50	675	22	15	15	42	375	18	15	15
49	637	21	15	15	41	337	17	15	15
48	600	21	15	15	40	300	17	15	15

(p.a.) = per annum.

(A) Addition for each full year's service in excess of that specified in column 3 or deduction for each full year wanting to complete that period of service—addition or deduction limited to five years in each case.

Twenty per cent. of all the rates of retired pay referred to above is variable with the cost of living, and the rates at present in course of payment are approximately 5½ per cent. below those given above.

DENTAL BRANCH.

The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of Surgeon Commander (D) is not open to them. They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work, and there is every opportunity for them to maintain a high standard of professional skill.

Entry is by competition, the Competitive Entrance Examination being similar in scope to the Final Qualifying Examination. Candidates are required to produce the usual certificates of birth, registration and of character, and must be physically fit for service anywhere. They must not be more than 28 years of age on the day of commencement of the entrance examination. An outfit allowance of £50 is payable to officers finally entered and commissioned.

Provision has been made for candidates who, at the time of passing the examination, hold or are about

Retirement and Retired Pay.

The following are the rates of pension and retired pay:—

1. Retired pay will consist of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible for retired pay.

2. The scale will be as follows, subject to the reduction of 5½ per cent. referred to below:—

(*a*) Service element.—£15 a year for each completed year of service as a medical officer.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant - Colonel	150	30	240
Colonel	290	50	390
Major-General ..	440	50	540
Lieutenant - General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together:—

	£		£
Captain and Subaltern ..	300	Colonel	800
Major	450	Major-General ..	1000
Lieutenant-Colonel ..	600	Lieutenant-General	1200

The above rates are those laid down in the Pay Warrant. They have been reduced by 5½ per cent. as from July 1st, 1924. (See footnote *.)

3. Officers with 8½ and less than 20 years' service as medical officers may be permitted to retire with a gratuity varying from £1000 to £2500.

Arrangements have been made for the appointment of Consultants in both Medicine and Surgery and the ranks of Colonel and Major-General will now be open to such Officers. The duties of these Officers are to visit all Commands and advise the Director-General, as the result of their inspections on the spot, with regard to the professional work being carried on in the hospitals, and the degree of efficiency attained by the personnel with whom they are respectively concerned. This should ensure a high standard of performance if only because of the satisfactory feeling that good work will not by accident remain unnoticed.

The present holders of these posts are Consultant in Surgery, Colonel J. W. West, late Professor of Surgery at the Royal Army Medical College; Consultant in Medicine, Colonel J. C. Kennedy, late Professor of Tropical Medicine at the Royal Army Medical College.

THE ARMY DENTAL CORPS.

The Corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force and personnel is required to serve under either force and be interchangeable. Officers and other ranks posted for duty with the Royal Air Force will perform their duties under the Regulations of the Royal Air Force for the employment of dental personnel, but the conditions in the following tables apply equally in either force. Promotion is carried out on one general list. The regulations for admission to the Army Dental Corps should be obtained from the Secretary, War Office, and carefully studied.

OFFICERS: *Appointment and Promotion.*

1. Commissions as lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

2. An officer shall be eligible for promotion to the rank of captain on completion of three and a half years' service in the Corps provided he has previously qualified in such manner as may be prescribed by the Army Council.

3. Promotion to the rank of major and lieutenant-colonel to fill the establishments laid down from time to time for those ranks, shall be made by selection of the Army Council, provided the officer has previously qualified for promotion to those ranks in such manner as may be prescribed by the Army Council.

4. Certain appointments in the rank of lieutenant-colonel and major have been approved to fill the establishment. The remainder of the appointments are in the rank of lieutenant, except in cases where service of three and a half years or more has been given as a temporary dental officer when the rank of captain will be given. Service as a temporary dental officer will count towards the three and a half years for promotion to captain.

Pay.

The following are the rates for officers of the Army Dental Corps:—

	Per diem. £	s.	d.
Lieutenant	0	18	10
Captain	1	3	8
Captain after 6 years' total service ..	1	5	0
Captain „ 10 „ „ „	1	7	0
Major	1	11	2
Major, after 15 years' total service	1	15	10
Lieut.-Colonel	2	4	10
Lieut.-Colonel after 20 years' total service ..	2	7	4
Lieut.-Colonel „ 25 „ „ „ ..	2	9	8

These rates are 5½ per cent. below those shown in the Pay Warrant, 1922. The latter, when granted, were made subject to revision to an extent not exceeding 20 per cent., according to variation in the cost of living. The next revision takes place on July 1st, 1927.

Allowances.

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the R.A.M.C.

Retirement and Retired Pay or Gratuity.

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' service.

(3) Earlier retirement on gratuity may be allowed:—

After 8½ years' service in the Corps, gratuity of	£1000.
„ 15 „ „ „	£1800.
„ 18 „ „ „	£2500.

(4) Retirement will be compulsory at the age of 55 years.

(5) A lieutenant who does not qualify for promotion within three and a half years' service in the Corps will be retired; and a captain who fails to qualify for promotion to major within twelve years' service in the Corps will be retired on any gratuity for which he may be eligible under paragraph 3.

Other Ranks.

The rates of pay of warrant officers, non-commissioned officers and men are those provided in the Warrant of Sept. 13th, 1919, *vide* Army Order 324 of 1919.

The aim of the Corps is the prevention of wastage of man power on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier will be re-inspected at least once a year and his dental efficiency maintained at the best standard possible. As recruits are not now enlisted unless they have sufficient natural teeth to enable them to masticate efficiently it is hoped that the conservative nature of the treatment they will receive will reduce considerably the percentage of artificial dentures required.

The "other ranks" of the Corps consist of dental mechanics and clerk orderlies. Training of dental mechanics has been proceeding for some time at the Central Dental Laboratory, Aldershot, and it is not proposed to open recruiting at present for this section. A limited number of clerk-orderlies is now being enlisted, and these men receive their training at the Royal Army Medical Corps Depôt.

ROYAL ARMY MEDICAL CORPS: PAY AND ALLOWANCES.

Rank.	Pay per diem.*	Rations†	Servant.	Married.			Unmarried.		Approximate yearly total.

* Pay Warrant rates less 5½ per cent. from July 1st, 1924, vide A.O. 93 and 204 of 1924. The Pay Warrant rates when granted were made subject to revision to an extent not exceeding 20 per cent., according to variation in the cost of living. The next revision takes place from July 1st, 1927.

† Rates of allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations.

administration eternally takes the *pas* of science. The Directorates in Pathology and Hygiene which were recently created in the R.A.M.C., and which we may say have proved a marked success, form a complete answer to such criticism, however just it was in the past. This scheme of creating Directorates permits specially selected men to rise from all ranks to Major-General on the strength of their scientific work. Hitherto, a few notable men being excepted, the rule in the R.A.M.C. has been that, whatever a man's qualifications or abilities, on attaining the rank of Lieutenant-Colonel, he must be prepared to go off into administrative work and leave his scientific duties to his juniors. If he preferred to remain working in bacteriology, in preventive medicine and hygiene, or in tropical diseases, for example, he could do so, but, except in extraordinarily fortunate circumstances for himself, he would find that his devotion to science had cost him all chances of further rise in his Service, promotion being reserved for the administrative billets. This now has all been changed, and the change has its expression in these Directorates. All ranks up to and including the rank of Lieutenant-Colonel can draw specialist pay and hold appointments carrying allowances. The following is the scale of additional pay and charge pay:—

Additional Pay and Charge Pay for Officers of the R.A.M.C.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under, within a limit of 5*s.* a day:—

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology, including Venereal Disease, 5*s.* daily.

Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 2*s.* 6*d.* daily.

Officers granted temporary higher rank while holding appointments in the services of hygiene and pathology will not be eligible for additional pay as specialists while holding such temporary rank.

(2) (*a*) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds	.. 2*s.* 6*d.* daily.	300 beds	.. 7*s.* 6*d.* daily.
150 „	.. 5*s.* 0*d.* „	500 „	.. 10*s.* 0*d.* „

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates.

	Daily. *s.* *d.*
(*b*) Senior medical officer, Royal Arsenal not exceeding	10 0
(*c*) Officer in command of the depôt, Royal Army Medical Corps	5 0
(*d*) The senior officer of Our Army Medical Service with an army in the field: A rate to be fixed by Our Army Council according to the magnitude of the charge.	
(*e*) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5 0
(*f*) Adjutant R.A.M.C. Depôt	5 0
(*g*) Adjutant R.A.M.C. (Territorial Army)	2 6

Further, an officer, graded as a specialist, and appointed to the charge of a medical or surgical division of a general hospital may be allowed to retain his additional pay and to draw the rate of charge pay laid down for the officer in charge of a medical or surgical division of a general hospital, provided that the total of additional and charge pay so drawn does not exceed the rate of charge pay drawn by the officer in charge of the hospital. With this exception charge pay and additional pay as specialist will not be issuable concurrently. It may be here pointed out that the distinction between scientific and administrative work is largely verbal. Take the conduct of a large hospital—is it possible to separate the scientific routine which is designed to ensure progressive therapeutics from the administrative work which provides and maintains the premises and service, and selects and oversees the personnel?

Under the conditions enumerated the possibilities for good workers is very great in the R.A.M.C.; they will attain to positions of proper trust and emolument by scientific work. This should much improve recruiting among the officers of the R.A.M.C. But there will almost certainly follow arrangements by which all special medical service will receive higher consideration in the Corps. Not only is there in the work of the Army Medical Department scope for original labour and research in tropical disease, in preventive medicine, and in bacteriology, as well as in the vast clinical field open to the specialist in medicine, surgery, or gynæcology, in venereal disease, in ophthalmology, and so on, but it is proposed to develop a scheme whereby child welfare shall be undertaken systematically by the R.A.M.C. A scheme of this sort is already running successfully at Aldershot, and we see in this direction a fine opening for preventive medicine, and one which should bring the officers of the R.A.M.C. into touch with the soldiers in a valuable and intimate manner.

The above schemes for the stimulation of purely professional work among officers of the Corps must not be taken to imply that instruction in administrative work has been overlooked. One of the lessons of the war was that good administration must exist for the fullest benefit to be obtained from the professional talent available. The necessity of training officers who may display capacity for organisation and administration has not been lost sight of, and there are many appointments of varying degrees of importance and responsibility open to officers who desire to take up this side of the Corps' duties.

TABLE I.—AIR FORCE MEDICAL SERVICE: RATES OF PAY.

1. The following is an outline of the emoluments issuable to officers of the Medical Branch of the Royal Air Force at present. Allowances are issued only when accommodation, fuel, light, rations and personal attendance are not available and the rates vary in different countries.

—	Pay. Daily. Standard rate.	Pay. Daily. Rate from July 1st, 1924.	Pay. Yearly. Rate from July 1st, 1924.	Allowances (daily rate at home). Lodging.	Allowances. Fuel and light (average). Married.	Allowances. Fuel and light (average). Single.	Allowances. Ration.	Allowances. Servant.	Total allowances at home. Daily. Married.	Total allowances at home. Daily. Single.	Total allowances at home. Yearly. Married.	Total allowances at home. Yearly. Single.	Total emoluments at home. Daily. Married.	Total emoluments at home. Daily. Single.	Total emoluments at home. Yearly. Married. 2. The above rates of pay are liable to revision. The standard rates were drawn up in 1919 in the light of the then high cost of living, and 20 per cent. of each of the standard rates is regarded as detachable and subject to alteration, either upwards or downwards as the cost of living rises or falls. The first revision took effect from July 1st, 1924, when a reduction of approximately 5½ per cent. was made in the standard rates. Subsequent revisions will be made at intervals of three years.

3. It must, however, be clearly understood that while every consideration will be given to the reasonable and legitimate interests of individuals, it will be competent for the Air Council at any time to modify the regulations under which the emoluments of the R.A.F. are drawn, and no Officer will be entitled to claim any pay, gratuity, or other advantage conferred by a provision being at any time added to, varied, or cancelled.

4. For the purpose of the issue of allowances a "married officer" is one who is married and has attained the age of 30 or the substantive rank of Squadron Leader or who, irrespective of age and rank, was married on or before Sept. 15th, 1919, and was serving in the Royal Air Force on June 8th, 1922.

5. As allowances are given for specific purposes, the cost of which may vary at comparatively short intervals, the rates of allowances are liable to be reviewed as circumstances may require.

6. A colonial allowance is granted in certain commands abroad in aid of the expenses of living in the countries where the cost is higher than in the United Kingdom.

7. For periods of service given under Indian administration and payment, officers will come under the rates and conditions authorised from time to time by the Indian Government in so far as these rates and conditions may differ from those in this scheme. The Indian rates are at present under review.

INDIAN MEDICAL SERVICE.

WE cannot foretell how and to what extent the Indian Medical Service will be affected by the report of the Royal Commission on the Superior Civil Services in India. The report is the outcome of the Indian reform scheme, the essence of which is an increasing participation by Indians in the government of the country, and as far as the Indian Medical Service is concerned, the recommendations of the Commission can be summarised almost in a sentence. Contrary to the recommendation of the Verney-Lovett Committee, the Commission has recognised that the medical needs of both the British and Indian armies in India should be provided for in future by the Royal Army Medical Corps (India) which should absorb the Indian Medical Service, no attempt being made to perpetuate that service as at present constituted. This recommendation is in accordance with the scheme elaborated by Sir Charles Burtchaell in 1919, and printed at length as an appendix to the Commission's report. At the same time, a new civil medical service is to be constituted in each province recruited by competitive examinations held both in England and India. To meet the medical needs of British officers in the Civil Service and their families a minimum number of British officers is to be maintained in this civil medical service, the limit to be prescribed for each province by the Secretary of State, on whom in the last resort is to rest the responsibility for their maintenance. Of this British element, one half, or the number required for the military reserve (whichever is the larger), is to be reserved for British officers seconded from the R.A.M.C., the remainder being those succeeding in competitive examination. It is further recommended that, subject to the existing rights of present members of the Indian Medical Service, all scientific chairs in Government colleges and hospitals shall be thrown open to all candidates, the clinical chairs alone being reserved for members of the civil medical services so far as suitable candidates are available.

We set out last year in detail the conditions of pay, leave and pension under which appointments were then being made to the Service. These conditions are no longer relevant to new appointments, for, if the recommendations of the Lee Commission are accepted, no more appointments will be made under them, and meanwhile recruitment has been temporarily suspended. It should be added, however, for the information of those already in the Service, that the basic pension rates there stated have been made liable to a "cost of living" reduction with effect from July 1st, 1924. The amount of reduction has not yet been fixed, but will not exceed 5½ per cent.

Whatever the ultimate arrangements may be, the necessity will remain to provide a European medical service in India so long as Europeans are employed in the various departments of the Civil Service. The time cannot be far distant when the Government will again be obliged to call for applicants for this Service, the terms of which are presumably now under discussion.

WOMEN'S MEDICAL SERVICE FOR INDIA.

THIS service is open to fully qualified medical women of British or Indian nationality who desire to carry on work in India. With the present amount of Government subsidy the number of medical officers is limited to 40. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals. Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare; medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Rates of pay are as follows:—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	English equivalent* per annum.
1 to 3	Rs.100	Rs.450	£440
4 to 6	,,	Rs.500	£480
7 to 9	,,	Rs.550	£520
10 to 12	,,	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600
16 to 18	,,	Rs.700	£640
19 to 21	,,	Rs.750	£680
22 to 24	,,	Rs.800	£720
over 24	,,	Rs.850	£760

* At rupee value 1s. 4*d*.

Furnished quarters are provided, representing an additional Rs.150 per mensem.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.200 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years. Study-leave on two-thirds pay is granted to the extent of 12 months in the total service. There is a provident fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent. which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Major-General J. B. Smith, India Office, Whitehall, London.

AIR FORCE MEDICAL SERVICE.

THE Royal Air Force Medical Service offers a career for medical men which should prove both attractive and interesting. The rates of pay and allowances are good, and a new field of scientific interest is opened up by the manifold problems which the circumstances of aviation produce. The physical and mental fitness for, and reaction to, the varied conditions under which the flying personnel perform their functions provide much scope for research. As promotion to the higher ranks of the Service is by selection, and as a certain proportion of the higher ranks will be reserved for purely scientific, as opposed to administrative, appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration.

COLONIAL MEDICAL SERVICE.

IN the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, and territories under their control, such as Papua and the Cook Islands, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; appointments in Egypt and the Soudan are regulated from the Foreign Office; in Southern Rhodesia the appointments are made by the local Government, but the British South Africa Company, London Wall Buildings, E.C., act as their agents in this country; in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E.C., for appointments; and those in Sarawak are in the hands of H.H. the Rajah. Much valuable information will be found in the "Professional Handbook," Part II., issued by the Oversea Settlement Office, 3 and 4, Clement's Inn, Strand, London, W.C. 2, price 9*d*.

As a general rule, each Colony or Protectorate has its own public service distinct from that of every other; and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another. There are three exceptions to this rule: (*a*) The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, is one service. (*b*) The East Africa Medical Service, which serves Kenya, Uganda, Zanzibar, Nyasaland, Somaliland, and the Tanganyika Territory is one service. (*c*) In practice the medical services of the Straits Settlements and the Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States or vice versa.

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the Secretary of State for the Colonies are (*a*) the West African—viz., Nigeria, the Gold Coast, Sierra Leone, and the Gambia; (*b*) the East African—viz., the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, the Tanganyika Territory, and Northern Rhodesia; (*c*) the Eastern—viz., Ceylon, the Straits Settlements and Malay States, Hong Kong, Mauritius, and Seychelles; (*d*) the West Indian—viz., British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, British Honduras, and the Bahamas; (*e*) Fiji and the Western Pacific, Cyprus, Malta, Gibraltar, St. Helena, Bermuda, and the Falkland Islands; and (*f*) Palestine.

In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. Appointments in Malta are all filled locally. Vacancies occur most regularly and frequently in the West African Medical Staff, the East African Medical Service, and the Straits Settlements and Malay States.

All applicants for medical appointments in the gift of the Secretary of State for the Colonies should be between the ages of 23 and 35,[1] and must be doubly qualified; preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and professional competence will be required, and every officer before being definitely appointed will be medically examined by one of the consulting physicians of the Colonial Office: Sir J. Rose Bradford, 8, Manchester-square, London, W. 1; Sir J. Hawtrey Benson, 57, Fitzwilliam-square, Dublin; Lieut.-Colonel Glen Liston, C.I.E., I.M.S., 33, Comely Bank, Edinburgh; and Dr. R. H. Kennan, 2, St. James's-road, Liverpool. Applications for such appointments must be addressed to the Private Secretary (Appointments), Colonial Office, Downing-street, S.W. 1.

EAST AFRICAN MEDICAL SERVICE.

The Medical staffs of the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika Territory form one service, the members of which are liable to be posted to any of the Dependencies as the exigencies of the service may require. The preferences of individual officers are, however, taken into consideration as far as possible.

Selected candidates are appointed as medical officers on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory. Unless the Secretary of State directs to the contrary, they are required to attend a course of instruction at the London or Liverpool School of Tropical Medicine before taking up their appointments. If such a course is not taken before proceeding to East Africa, they are required to take it during their first leave of absence. Medical officers (but not medical officers of health) are permitted to take private practice, on the understanding that they give precedence to their official duties. It must be understood that, as a general rule, additions to their income from this source are not likely to be substantial.

The currency in different Dependencies in East Africa varies. In Kenya, Uganda, and the Tanganyika Territory, an East African shilling (one-twentieth of a pound sterling) is the standard coin. Salaries and sterling allowances are issued locally in respect of resident service at a fixed rate of 20 shillings to the pound sterling. A special local allowance, averaging 15 per cent. of sterling salaries and allowances is at present issued in respect of resident service. The question of the continuance or otherwise of the allowance will be subject to review on Dec. 31st, 1924. In Zanzibar and Somaliland the Indian rupee is the standard coin, and for the present sterling salaries and allowances are issued at a fixed rate of 15 rupees to the pound. No local allowance is paid. In Nyasaland sterling currency is used, and no local allowance is paid.

Medical officers are provided with quarters free of rent (but not of rates or other similar outgoings), if quarters are available; if quarters are not available, the Government may provide temporary accommodation or alternatively, at the discretion of the Government, an allowance in lieu of quarters calculated at 15 per cent. of the initial salary of an officer's appointment may be paid. The salary of a medical officer is £600 per annum, rising by annual increments of £25 to £900 per annum, with efficiency bars at £700 and £800.

Medical officers in East Africa are permitted to retire with gratuity, if they wish, instead of waiting to retire on pension as follows: (*a*) After nine years' service, of which at least six must have been spent in East Africa, £1000; (*b*) after 12 years' service, of which at least eight must have been spent in East Africa, £1250. If an officer elects to retire with gratuity, he thereby forgoes all claim to pension.

The grades and salaries (apart from ordinary medical officers) in the medical departments are as follows:—

Kenya: Principal Medical Officer, £1200; Deputy Principal Medical Officer, £1000; Principal Sanitation Officer, £1000; Resident Surgeon, Nairobi European Hospital, £900–50–1000; Senior Medical Officers, £800–25–900; Sanitation Officers, £800–25–900; Bacteriologist, £900–50–1000; First Assistant Bacteriologist, £800–25–900; Second Assistant Bacteriologist, same scale as Medical Officer.

Uganda Protectorate: Principal Medical Officer, £1200; Deputy Principal Medical Officers (two, one being for Native services), £1000; Principal Sanitation Officer, £1000; Resident Surgeon, Kampala Hospital, £900; Sanitation Officer, £800–25–900; Senior Medical Officers, £800–25–900;

---

[1] In the case of East Africa, preference will be given to candidates who are over 25 years of age. In the case of Fiji and the Western Pacific, preference will be given to candidates who are under 30. At the present time, however, no definite age-limits are insisted on; but officers over the age of 35 must be prepared to serve, if required, on a temporary and non-pensionable footing.

The establishment will consist partly of permanent and partly of short-service officers. An officer will on first entry be granted a short-service commission for a period of two years on the active list (which may be extended to four years at the discretion of the Air Council on recommendation of the Director of Medical Services), and of four years in the Reserve of Air Force officers. The periods of service on the active list are under review. Selections for permanent commissions will be made from officers holding short-service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

Short-service officers who are approved for permanent commissions, but for whom there are not vacancies in the Royal Air Force Medical Service, may, under certain conditions, be considered for transfer to the Royal Army Medical Corps, counting their time served in the Royal Air Force towards increments of pay and retired pay in the Royal Army Medical Corps.

Officers who have been selected for permanent commissions may be granted leave for a period not exceeding nine months for post-graduate study in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such leave will be granted during the first six years of permanent service, and during such leave officers will receive full pay and allowances.

New entrants for the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will be promoted to the rank of Squadron Leader after 10 years' total service. Accelerated promotion may be carried out, in a limited number of cases, of officers who show exceptional ability after the completion of eight years' service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after 16 years' total service, and to that of Group Captain by selection at any period after 22 years' service.

There will be no competitive examination on entry; candidates must be under 28 years of age, British subjects, the sons of British subjects, and of pure European descent, be nominated by the Dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce—

1. Birth certificate.
2. Medical registration certificate.
3. A declaration containing the following information:—

(a) Age and place of birth.

(b) That he is a British subject and the son of British subjects, and of pure European descent.

(c) That he is ready to engage for general service at home or abroad as required.

(d) The qualifications he is possessed of, and what medical or other appointments he has held (if any).

(e) That he is willing to fly whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interefere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

An officer granted a short-service commission who, at the time of application for such commission held or was about to hold a resident appointment in a recognised civil hospital, may be seconded for the period not exceeding one year from the date of the commission during which he shall hold such appointment. Whilst seconded he will not receive pay from Air Ministry funds, but the period of secondment will otherwise count as service in the Royal Air Force, provided that he will be required to serve for a minimum period of two years on the active list from the date on which he ceases to be so seconded.

Uniform and Equipment.

Medical officers will be required to provide themselves with the uniform of their rank and with the distinguishing badge of the Royal Air Force Medical Service. They will be required to provide themselves with service dress and mess dress. The provision of full dress is entirely optional at present.

An allowance of £50 will be made towards the cost of uniform for officers who have not previously held commissions in the Royal Navy, the Army, the Indian Army, the Royal Marines, or the Royal Air Force, or any of the auxiliaries of these forces. An allowance of £25 will be made for officers with previous commissioned service in the Royal Navy, the Army, the Indian Army, the Royal Marines, or any of the auxiliaries of these forces, but not in the Royal Air Force or its auxiliaries.

The rates of pay are as shown in Table I.

The standard scale of retired pay for Group Captains and lower ranks is given in the following table:—

TABLE II.

Age.	Service counting for retired pay.	Standard rate of retired pay.	Addition for each extra year of service.*	Reduction for each deficient year of service.*
		£	£	£
55	24	790	22	15
54	24	765	22	15
53	23	742	22	15
52	23	720	22	15
51	22	697	22	15
50	22	675	15	15
49	21	637	15	15
48	21	600	15	15
47	20	562	15	15
46	20	525	15	15
45	19	487	15	15
44	19	450	15	15
43	18	412	15	15
42	18	375	15	15
41	17	337	15	15
40	17	300	15	15

* Limited to five years.

Group Captains retire at 55; maximum retired pay £900.
Wing Commanders retire at 51; maximum retired pay £600.
Squadron Leaders retire at 48; maximum retired pay £500.

There will be a minimum qualifying period for retired pay of 20 years.

The rates of retired pay given above (including the maximum rates) are standard rates which will be subject to revision as stated in paragraph 2 under Table I. The revision will apply to all retired pay which is being drawn at the date of revision as well as to subsequent awards.

Gratuities.

Short-service officers will receive gratuities on the scale of £100 for each of the first two complete years of service, and £150 for each of the third and fourth complete years. These gratuities will not be payable to officers granted permanent commissions, but the period of service under the short-service commission will count for retired pay.

Medical officers holding permanent commissions may, at the discretion of the Air Council, be allowed to withdraw from the Service after ten years' service with a gratuity of £1250 or after 16 years with a gratuity of £2000 in lieu of retired pay.

Allowances.

The usual allowances will be payable to medical officers under the same conditions as to officers of other branches of the Royal Air Force.

In addition to a chief medical officer (£800 a year, rising to £1000), a medical superintendent, Colonial Hospital (£650–£900, inclusive of allowances as medical officer of health and officer in charge of the Medical School), and a medical superintendent, Makogai Leper Asylum (£600 rising to £800), there are in Fiji 11 medical officers, five of whom are also district commissioners. The salaries in Fiji are subject to temporary increases, the rate of bonus at the present time being 15 per cent. of the salary with the addition of £22 10*s.*

The staff in the British Solomon Islands Protectorate consists of one senior medical officer (£650 rising to £750) and two medical officers (£550 rising to £650). In the Gilbert and Ellice Islands Colony there is one medical officer in charge (£650 rising to £750). Officers may be transferred from Fiji to the Western Pacific at the discretion of the Secretary of State.

Cyprus.—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £900, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s.* *per diem* forage allowance. There is also a medical officer of health on £600, rising by £20 increments to £720 without private practice; these are the only medical appointments in the island which are open to English candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £750, and private practice. There are also two assistant surgeons with a salary of £720 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The colonial surgeon at present receives £300 per annum, £20 fees as health officer, and £30 horse allowance. Private practice is allowed. A temporary bonus of 20 per cent. is at present being paid to the colonial surgeon, who further receives an allowance of £67 per annum from the Administration. The assistant colonial surgeon at present receives £550 a year and a horse allowance, but the salary may be revised on the occurrence of a vacancy. No private practice without special permission of the Governor.

Falkland Islands.—There are two appointments. The colonial surgeon is paid at the rate of £600 per annum, with free furnished quarters. The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters. Private practice is shared between the colonial surgeon and the assistant colonial surgeon. The office of colonial surgeon is pensionable.

Palestine.[2]—The grades and salaries of superior appointments in the Department of Health are: Director, £E1100–50–1400, plus £E100 expatriation allowance. Deputy director, assistant director (laboratory section), and senior medical officer (Jerusalem-Jaffa district) £E800–50–1100 plus £E100 expatriation allowance. Deputy assistant director, chemical analyst, three senior medical officers, and medical officer (Jerusalem-Jaffa district) £E550–25–750 plus £E50 expatriation allowance. The remainder of the staff is recruited locally. The salaries of the two highest grades will be reduced as vacancies occur.

LEAVE AND PENSIONS.

Leave and Passages.—Leave of absence in East Africa on full salary is granted in the normal case after a tour of residential service (of not less than 20 and not usually more than 30 months) to an amount of five days for each completed month of residence (or 2½ days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro, for which full pay is also given. Officers serving in Uganda, Zanzibar, and the Tanganyika Territory, or in certain stations in Kenya and Nyasaland, are allowed six (or three) days' leave in respect of each month of service instead of five (or 2½) days' leave respectively. In Somaliland special leave regulations exist which provide for an officer taking leave after a shorter tour of service than in other parts of East Africa. Free first-class passages are provided for the officer on first appointment and on leave.

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half-pay may be granted on special grounds. Up to the end of 1923 free passages are granted on first appointment and on leave, but the continuance of this privilege beyond that date is uncertain; but free passages on first appointment or transfer are granted permanently for officers with salary under £800 per annum.

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of six years' resident service without any special grounds. It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months [3] in any two years. In British Guiana officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay leave may be taken in addition to six months' full-pay leave.

On first appointment an officer whose salary and fees together do not exceed £800 a year will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. An officer taking leave out of the Colony has in most cases to provide his own passages.

Pensions.—*East Africa.*—Officers on the pensionable establishment retire on attaining the age of 50 years or after 20 years' East African service, whichever is earlier; but they may be retained in the service, with their own consent, for such further period as the Government may recommend. Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-sixtieth of pensionable emoluments—i.e., salary and value of free quarters[4]—at the time of retirement, two years' service being reckoned as three years for this purpose, subject to an average of emoluments for the last two years before retirement instead of the actual emoluments at the time of retirement being taken as the basis for calculation in certain circumstances.

Other Colonies.—In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he

---

[2] £1 Egyptian (of 100 piastres) is equivalent to £1 0s. 6d. sterling.

[3] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years.

[4] The value of free quarters for pension purposes is normally taken as 15 per cent. of the minimum salary of the grade in which an officer is serving at the time of retirement; but as a special temporary concession it will be taken as 30 per cent. of such salary in the cases of officers retiring on or after Jan. 1st, 1922. This arrangement will be liable to review after it has been in force for two years.

Bacteriologist, £900–50–1000; Assistant Bacteriologist, same scale as Medical Officer.

Nyasaland Protectorate: Principal Medical Officer, £1000. Senior Medical Officer, £800–25–900; Sanitation Officer, £800–25–900.

Zanzibar Protectorate: Principal Medical Officer, £1000; Senior Medical Officer of Health, £800–25–900.

Somaliland Protectorate: Senior Medical Officer, £800–25–900.

Tanganyika Territory: Principal Medical Officer, £1200; Deputy Principal Medical Officer, £1000; Senior Sanitary Officer, £1000; Director of Laboratory, Dar-es-Salaam, £800–25–900; Senior Medical Officers, £800–25–900.

The medical officers of health are usually selected from the medical officers in the permanent establishment. They receive special non-pensionable allowances of £50 or £100 a year according to station.

ASIA.

Straits Settlements and Federated Malay States.—European medical officers are appointed on the following scale of salaries: $440 per mensem, rising to $480 per mensem during three years' probation; then, if they are placed on the pensionable establishment, rising to $500 per mensem, and thence by annual increments of $25 per mensem to $800 per mensem, with a strict efficiency bar at $600 per mensem. This scale of salaries has been fixed on the supposition that medical officers join the service at about the age of 27. Above the concluding figure of $800 per mensem there are certain higher appointments as follows: Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $1200 per mensem. Class A: seven posts at $1050 per mensem. Class B: nine posts at $850, rising by $30 to $1000 per mensem.

The following temporary allowances are at present paid to all officers recruited from Europe in the Government Services of the Straits Settlements and Federated Malay States: unmarried officers, 10 per cent. of salary; married officers, 20 per cent. of salary. Private practice by Government medical officers is not allowed. They may, however, do, and receive fees for, consultative work, under conditions approved by the Government. Information about general conditions in Malaya is obtainable from the Malay States Information Agency, 88, Cannon-street, E.C. 4.

Seychelles.—The chief medical officer receives Rs.6000 and Rs.300 in fees. There are two assistant Government medical officers, one receiving Rs.5500 and Rs.500 house allowance, and one receiving Rs.5000. A small permanent increase of 5 per cent. on these salaries has been given as from Jan. 1st, 1921.

Hong-Kong.—The present establishment of the medical department is: principal civil medical officer, £1000–£50–£1200; five medical officers, £600–£25–£1000; health officer of the port, £600–£25–£1000; second health officer of the port, £600–£25–£1000; bacteriologist, £700–£25–£1000. A temporary allowance on a scale varying with the sterling exchange value of the dollar is at present payable. Salaries are converted locally at the rate of 2*s.* = $1. Free quarters are not provided, but in certain instances a rent allowance is paid by the Government.

AMERICA.

British Guiana.—There are the following posts in the medical service of the Colony: one surgeon-general, £1000–£1200 per annum, with consulting practice; one bacteriologist and pathologist, £450–£700 (increment £50), with £50 allowance in lieu of fees; 34 medical officers at £500–£25–£700. Some of the senior posts also carry duty allowances (varying from £50 to £300 per annum) and quarters. All the junior appointments in which private practice is not allowed carry duty allowances. Private practice is allowed in certain cases.

Trinidad and Tobago.—In Trinidad and Tobago there are over 40 appointments. Under the terms of the Ordinance regulating the medical service, officers are appointed in the first instance on two years' probation as supernumeraries and are eligible for appointment as Government medical officers at the end of this period. Supernumeraries receive a salary of £400 per annum with furnished quarters, and are usually attached to the Government hospital. Government medical officers receive salary at the rate of £400 per annum with annual increments of £25 accruing from the date of first appointment as supernumerary medical officers, until reaching the maximum of £600. Most are employed as district medical officers, with private practice, a residence or a rent allowance of £50, a horse allowance or motor allowance averaging £110 (except in one district). Officers employed in institution work receive allowances in lieu of private practice varying from £50 (and furnished quarters) to £300. In no case therefore do the emoluments on first appointment amount to less than £550 a year and furnished quarters. In a few districts a system has been introduced by which the work is performed by private practitioners under temporary contracts. There is good scope for private practice in all medical districts. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent).—There are over 25 appointments. The colonial surgeon, Grenada, receives £650–£800. The chief medical Officer, St. Lucia, receives £600–£700 plus forage and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government vary from £400–£500, and with allowances in certain cases. The Governor has the power to transfer a medical officer from one island to another at his discretion. The appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The appointments are of the same nature as in the Windward Islands and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary varying from £312 to £400, according to station, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands, and in certain districts may be required to perform magisterial duties. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also as a rule, allowed private practice. The chief medical officer, St. Kitts, receives £700–£25–£750 without private practice.

British Honduras.—There are seven medical appointments (besides the principal post of colonial surgeon) at a salary of $2430 per annum. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The value of the dollar is approximately the same as that of the United States dollar.

OTHER OVERSEAS APPOINTMENTS.

Fiji and the Western Pacific.—In Fiji the Government medical officers receive a salary of £400, rising by annual increments of £25 to £600, with partly furnished quarters, or a house allowance of £50. In some districts a medical officer is also a district commissioner, with an additional allowance of £150. They are allowed private practice, on the understanding that their official duties are not neglected. Private practice, however, cannot be guaranteed, and in most districts it is very small in amount. Where no private practice exists, a duty allowance of £50 is granted. They are required either to take charge of hospitals or of districts, at the discretion of the authorities. The posts are pensionable.

In addition to a chief medical officer (£800 a year, rising to £1000), a medical superintendent, Colonial Hospital (£650–£900, inclusive of allowances as medical officer of health and officer in charge of the Medical School), and a medical superintendent, Makogai Leper Asylum (£600 rising to £800), there are in Fiji 11 medical officers, five of whom are also district commissioners. The salaries in Fiji are subject to temporary increases, the rate of bonus at the present time being 15 per cent. of the salary with the addition of £22 10*s*.

The staff in the British Solomon Islands Protectorate consists of one senior medical officer (£650 rising to £750) and two medical officers (£550 rising to £650). In the Gilbert and Ellice Islands Colony there is one medical officer in charge (£650 rising to £750). Officers may be transferred from Fiji to the Western Pacific at the discretion of the Secretary of State.

Cyprus.—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £900, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s*. per diem forage allowance. There is also a medical officer of health on £600, rising by £20 increments to £720 without private practice; these are the only medical appointments in the island which are open to English candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £750, and private practice. There are also two assistant surgeons with a salary of £720 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The colonial surgeon at present receives £300 per annum, £20 fees as health officer, and £30 horse allowance. Private practice is allowed. A temporary bonus of 20 per cent. is at present being paid to the colonial surgeon, who further receives an allowance of £67 per annum from the Administration. The assistant colonial surgeon at present receives £550 a year and a horse allowance, but the salary may be revised on the occurrence of a vacancy. No private practice without special permission of the Governor.

Falkland Islands.—There are two appointments. The colonial surgeon is paid at the rate of £600 per annum, with free furnished quarters. The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters. Private practice is shared between the colonial surgeon and the assistant colonial surgeon. The office of colonial surgeon is pensionable.

Palestine.[2]—The grades and salaries of superior appointments in the Department of Health are: Director, £E1100–50–1400, plus £E100 expatriation allowance. Deputy director, assistant director (laboratory section), and senior medical officer (Jerusalem-Jaffa district) £E800–50–1100 plus £E100 expatriation allowance. Deputy assistant director, chemical analyst, three senior medical officers, and medical officer (Jerusalem-Jaffa district) £E550–25–750 plus £E50 expatriation allowance. The remainder of the staff is recruited locally. The salaries of the two highest grades will be reduced as vacancies occur.

LEAVE AND PENSIONS.

Leave and Passages.—Leave of absence in East Africa on full salary is granted in the normal case after a tour of residential service (of not less than 20 and not usually more than 30 months) to an amount of five days for each completed month of residence (or 2½ days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro, for which full pay is also given. Officers serving in Uganda, Zanzibar, and the Tanganyika Territory, or in certain stations in Kenya and Nyasaland, are allowed six (or three) days' leave in respect of each month of service instead of five (or 2½) days' leave respectively. In Somaliland special leave regulations exist which provide for an officer taking leave after a shorter tour of service than in other parts of East Africa. Free first-class passages are provided for the officer on first appointment and on leave.

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half-pay may be granted on special grounds. Up to the end of 1923 free passages are granted on first appointment and on leave, but the continuance of this privilege beyond that date is uncertain; but free passages on first appointment or transfer are granted permanently for officers with salary under £800 per annum.

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of six years' resident service without any special grounds. It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months[3] in any two years. In British Guiana officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay leave may be taken in addition to six months' full-pay leave.

On first appointment an officer whose salary and fees together do not exceed £800 a year will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. An officer taking leave out of the Colony has in most cases to provide his own passages.

Pensions.—East Africa.—Officers on the pensionable establishment retire on attaining the age of 50 years or after 20 years' East African service, whichever is earlier; but they may be retained in the service, with their own consent, for such further period as the Government may recommend. Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-sixtieth of pensionable emoluments—i.e., salary and value of free quarters[4]—at the time of retirement, two years' service being reckoned as three years for this purpose, subject to an average of emoluments for the last two years before retirement instead of the actual emoluments at the time of retirement being taken as the basis for calculation in certain circumstances.

Other Colonies.—In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half-pay as half service. In a few cases the retiring age is 60 and the pension after ten years' service is ten-sixtieths instead of fifteen. In the Straits Settlements and Malay States, an officer may, with the consent of Government, retire at age 50. Pensions are calculated on a basis of length of service in months instead of years.

---

[2] £1 Egyptian (of 100 plastres) is equivalent to £1 0*s*. 6*d*. sterling.

[3] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years.

[4] The value of free quarters for pension purposes is normally taken as 15 per cent. of the minimum salary of the grade in which an officer is serving at the time of retirement; but as a special temporary concession it will be taken as 30 per cent. of such salary in the cases of officers retiring on or after Jan. 1st, 1922. This arrangement will be liable to review after it has been in force for two years.

WEST AFRICAN MEDICAL STAFF.

Applicants for appointment as medical officers in the West African Medical Staff (the higher grades will usually be filled by promotion from the lower) must be British subjects of European parentage and between 23 and 35 years of age; preference is given to candidates who are over 25 years of age. Applicants must possess a complete double qualification, and must be on the Medical Register. Passages for wives and children are not provided by the Government, and houses for the wives of junior medical officers are rarely available. Officers are not allowed to take their wives and young children out with them until they have acquired experience of the local conditions and have obtained the sanction of the Governor; and permission to bring out young children will only be given in the most exceptional circumstances.

Candidates whom it is proposed to select for appointment will have to be medically examined by one of the medical advisers of the Colonial Office (or, in the case of those residing in a Colony, by a medical officer appointed by the Colonial Government), and no appointment will be made unless the candidate is declared to be physically fit for service in West Africa. Candidates are allowed to express a preference for any particular Colony or Protectorate, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony or Protectorate at the discretion of the Secretary of State. Candidates who wish to be posted to the Northern Provinces of Nigeria should be able to ride. Transfers from one Colony or Protectorate to another will be made as seldom as possible. They should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred elsewhere, as the number of such transfers is exceedingly small.

Officers of the West African Medical Staff who may be transferred to pensionable appointments under the Crown elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided that they have been members of the staff for at least 12 months. Every officer selected for appointment is required to have himself revaccinated before proceeding to West Africa, unless one of the medical advisers of the Colonial Office certifies in any particular case that this is unnecessary.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for two or three months, either at the London School of Tropical Medicine, Endsleigh-gardens, Euston-square, N.W. 1, or at the Liverpool School of Tropical Medicine, University, Liverpool. The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £3 a week will be paid to them monthly in arrear for this purpose. A daily allowance of 5*s.* (but no salary) will be paid to each candidate monthly in arrear during the course, and may be continued subsequently up to the date of embarkation. He will be bound to refund them (1) if he declines to accept an appointment in any of the Colonies or Protectorates for which he may be selected by the Secretary of State; (2) if he fails to obtain a certificate in regard to progress and efficiency, or (3) if he relinquishes the West African Service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of the date of his arrival in West Africa.

If at the end of the session there exists no vacancy in the Staff to which a candidate can be appointed, he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy.

Leave of Absence.—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony. Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa. An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances; and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service. Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months.

Appointments and Salaries.—The Medical Services of the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria (Southern and Northern Provinces)—form one service under the name of the West African Medical Staff. All the medical officers for the service are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. The grades and emoluments of the Staff are at present as follows:—

The Director of the Medical and Sanitary Service, Nigeria, receives a salary of £1800 a year, with a duty allowance at the rate of £360 a year. The Director of Medical and Sanitary Service in the Gold Coast receives a salary of £1600 a year, with a duty allowance at the rate of £320 a year. The Director of Medical and Sanitary Service in Sierra Leone receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year. The Deputy Director of Medical and Sanitary Service, Nigeria, and the Deputy Director of Sanitary Service, Nigeria, receive salaries of £1500 a year, with duty allowances at the rate of £300 a year. The Deputy Director of Medical and Sanitary Service, Gold Coast, receives a salary of £1400 a year, with duty allowance at the rate of £280 a year. Assistant Directors Medical Service: There are nine appointments on this grade, six in Nigeria, two in the Gold Coast, and one (with the title of Deputy Director Medical Service) in Sierra Leone. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. The Assistant Director of Sanitary Service, Nigeria, the Deputy Director of Sanitary Service in the Gold Coast and the Deputy Director of Sanitary Service in Sierra Leone receive salary at the rate of £1300 a year, with duty allowance at the rate of £260 a year. Specialists: The number of these appointments is not fixed, officers of outstanding professional merit being eligible for appointment. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. After five years' approved service as such, the specialist officer is eligible to receive a salary at the rate of £1400 a year, with duty allowance at the rate of £280 a year. There are at present four officers appointed specialists in Nigeria and two in the Gold Coast. Senior Medical Officer: There are twenty appointments of this grade, with salary at the rate of £1000 a year, rising by annual increments of £50 to £1150 a year, and seniority allowance at the rate of £100 a year. The Senior Medical Officer, Gambia, is allowed "staff pay" of £150 a year, in addition to duty allowance, but he is debarred from private practice. Senior Sanitary Officer: There are six appointments of this grade, with salary at the rate of £1050 a year, rising by annual increments of £50 to £1200 a year, and a duty allowance at the rate of £210 a year. Medical Officer: The salary attached to this grade is at the rate of £660 a year, rising by annual increments of £30 to £720 a year. Then, if confirmed in the appointment, £720 a year, rising by annual increments of £40 to £960, with seniority allowance at the rate of £72 a year. Before passing £800, medical officers are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they draw their further increments up to £960 a year.

A medical officer who has served for three years on the maximum salary of this scale (£960) without obtaining promotion is eligible, if recommended by the Governor, to be placed on the scale £1000–£50–£1150, with £100 seniority allowance (as for Senior Medical Officers).

Special Appointments.—The director of the Medical Research Institute, Lagos, and the pathologist, Accra, receive a salary of £1300 a year, with a duty allowance of £260 a year, rising after five years' approved service to a salary at the rate of £1400 a year and duty allowance at the rate of £280 a year. Salary at the rate of £800 a year, rising by annual increments of £40 to £960 a year, is attached to about ten posts (those of assistant at the Medical Research Institute, Lagos, and medical officers of health at various places), irrespective of the seniority of the officer holding the appointment. In addition to the seniority allowance (£72 a year), staff pay at the rate of £150 a year is also attached to these posts; and the holder of the appointment draws half of the staff pay during leave of absence, the remainder being drawn by his locum tenens. The holders of these appointments are not allowed private practice.

Duty allowances, seniority allowance, and staff pay are not pensionable emoluments.

Increments.—Increments to salaries are payable only when the service of an officer during the period of employment qualifying for increment is approved.

Payment of Salaries.—Information as to the payment of officers' salaries or of monthly remittances to persons in England may be obtained from the Crown Agents for the Colonies, 4, Millbank, S.W. 1. All allowances are paid locally.

All officers of the staff, except directors, deputy directors, assistant directors, senior sanitary officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at the majority of stations, and no guarantee can be given that an officer will be posted to a station in which he will be able to practise privately. As a general rule, and subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the Staff.

Pensions and Gratuities.—Pensions and gratuities on retirement from the service are granted in accordance with the law and regulations of each individual Colony.

Fuller information can be obtained from the Private Secretary, Colonial Office, Whitehall, London, S.W. 1.

SPECIAL DIPLOMAS.

DIPLOMA IN TROPICAL MEDICINE.

ALTHOUGH a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Tropical Medicine, 5, Endsleigh-gardens, London, N.W. 1 (founded in 1899), which is a school of the University of London in the Faculty of Medicine.

University of Cambridge.—The examination for the Diploma in Tropical Medicine and Hygiene is divided into two parts. Part I. is held in Cambridge in April and Part II. in July in London. Candidates for Part I. are examined under the same regulations and in the same subjects as candidates for the Diploma in Public Health, but any qualification in medicine or surgery recognised by the proper authority of any country outside the British Dominions may be recognised. The subjects for Part II. are Medicine, Surgery, and Hygiene in their relation to Tropical Disease.

The examination will be partly in writing, partly oral, and partly practical or clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment). Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma (D.T.M. & H.) testifying to his knowledge and skill in tropical medicine and hygiene.

The fee for each part of the examination is £10 10s., and applications should be addressed to Mr. J. E. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.—The M.D. degree may be taken in tropical medicine at an examination held twice annually, for which a thesis may be submitted.

University of Liverpool.—The University grants a Diploma in Tropical Medicine. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The subjects of examination are (*a*) Tropical Pathology, Parasitology and Entomology; (*b*) Tropical and Applied Bacteriology; (*c*) Tropical Hygiene and Sanitation; (*d*) Tropical Medicine, including Ætiology, Symptoms, Diagnosis, and Treatment of Tropical Diseases. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. The fee for the full course of instruction is £21, with an extra charge of 10*s.* 6*d.* for the use of a microscope if required. Applications should be made to the Dean of the Medical Faculty, University of Liverpool. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The diploma of D.T.M. & H. Eng. is awarded on the results of an examination held thrice yearly in January, April, and July. Candidates must possess a registrable qualification, and produce evidence of having attended (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine in a recognised institution during not less than three months, (2) clinical practice of a recognised hospital for the same period. Conditions of study may be modified in the case of candidates of special experience. Fee for admission to the examination, £9 9*s.*, 14 days' notice of entry to the Secretary, Examination Hall, Queen-square, London, W.C. 1.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

THE Universities of Cambridge, London, Durham, Leeds, Manchester, and Edinburgh, and the Conjoint Board of the R.C.P. Lond. and R.C.S. Eng. now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies.

In London, courses of instruction for the Diploma in Psychological Medicine are given at the Maudsley Hospital, Denmark Hill, which has recently been definitely recognised as a school of the University of London. The course consists of two parts, and is adapted for the diploma of the Conjoint Board, the University of London, or the University of Cambridge. The fee for the whole course (Parts I. and II.) is 15 guineas, or for either part separately 10 guineas.

Appointments as clinical assistants are obtainable at the Maudsley Hospital. The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction. Inquiries as to lectures should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5; and as to clinical facilities, to the Medical Superintendent at the same address.

A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various Universities, is held at Bethlem Royal Hospital twice annually, during the spring and autumn. The fee for the full course is 15 guineas; for Part A separately 10 guineas, and for Part B separately 10 guineas. Communications should be addressed to the Physician-Superintendent, Bethlem Royal Hospital, London, S.E. 1. In addition clinical instruction in psychological medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 o'clock. The fee for post-graduates is 5 guineas for three months' attendance, but a reduction is made to those who attend the diploma course.

DIPLOMA IN OPHTHALMIC MEDICINE.

SPECIAL diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.—The diploma in ophthalmology (D.O.) is granted to registered medical practitioners after passing an examination, held annually in July, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course. Further information regarding these requirements may be obtained from the Dean of the School of Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in January and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a registrable qualification. Fee for admission to each part, £6 6*s.*

DIPLOMA IN TUBERCULOUS DISEASES.

A DIPLOMA in Tuberculous Diseases is given by the University of Wales. Candidates must possess a medical qualification registrable for practice in Great Britain and Ireland, and be not less than 25 years of age, and either (Category A) have held, for a period of not less than five years, whole-time appointments for work in tuberculosis; or (Category B) have held a registrable qualification to practise for at least one year, and presented (*a*) a certificate of satisfactory pursuance of a course of consecutive post-graduate study of the clinical and epidemiological aspects of tuberculosis of six months' duration at a recognised university, medical school, or hospital where such a course is given; or, alternatively, a certificate of one year's post-graduate work as a whole-time member of the staff of a tuberculosis hospital, sanatorium, or dispensary approved by the Ministry of Health, signed by the representative of the authorities for whom the work was performed or by the administrative medical officer concerned; (*b*) a certificate of satisfactory pursuance of a course of consecutive post-graduate practical study of the Pathology and Bacteriology of Tuberculosis of three months' duration at a tuberculosis laboratory or a recognised general laboratory where such a course is given; (*c*) a certificate of three months' satisfactory attendance at a tuberculosis institute or dispensary. The courses may be taken concurrently.

The examination is divided into two parts. An examination in each part will be held annually in the first week of July. The fee for examination is £10 10*s.* Applications should be made to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 15th.

DIPLOMA IN RADIOLOGY.

IN June, 1919, the University of Cambridge instituted a Diploma in Medical Radiology and Electrology to be taken by medical graduates after a course of study extending over a period of six months or more. The lecture course in Part I. consists of physics and electro-technics with photography; in Part II. of radiology and electrology—in each case with special reference to diagnosis and treatment. Six months' clinical experience is required in the electrical department of a hospital recognised by the committee for this purpose. Lecture courses are arranged twice a year alternately in Cambridge and in London. Candidates for the Cambridge course spend three months in Cambridge and the remainder in London or elsewhere. The next London course begins Oct. 1st, and the next Cambridge course Jan. 7th. Application to the Secretary, Dr. Shillington Scales, Medical Schools, Cambridge.

DIPLOMA IN PUBLIC HEALTH.

As usual we include in the Students' Number of THE LANCET an epitome of the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene or State medicine, as this discipline is variously called. Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council from 1902 to 1922. The new regulations, which came into force on Jan. 1st last, extend the period of study and postpone the granting of a diploma until at least two years from qualification.

Conjoint Board of the R.C.P. Lond. and R.C.S. Eng.—New regulations came into force on Jan. 1st, 1924, which apply to all candidates who have not commenced bonâ-fide study of Public Health in accordance with the above regulations before that date. They are as follows: The Examination consists of two Parts. Part I. will be held in the months of January, April, and June, and Part II. in the months of January, April, and July in each year. Candidates may enter for Parts I. and II. separately or at the same time, but they must pass Part I. before proceeding to Part II. The Examination in each part will be written, oral, and practical. Part II. will include a practical examination in Infectious Diseases, Food Inspection, and Inspection of selected

Premises. The Fee for admission to each Part of the Examination, which must be paid three days before that part commences, is £10 10*s*., except in the case of Candidates who possess the Licence, Membership, or Fellowship of the Royal College of Physicians of London, or the Membership or Fellowship of the Royal College of Surgeons of England, who will be required to pay £6 6*s*. only for each part. Candidates who fail to satisfy the Examiners in either part may present themselves again at the next Examination on payment of the same Fees. Candidates intending to present themselves for either part of the Examination must give 14 days' notice in writing to the Secretary, at the Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

Candidates will be admissible to Examination in Part I. on producing evidence :—

1. Of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery.

2. Of having attended during a period of not less than five months at an Institution recognised by the Examining Board in England, practical instruction in (*a*) Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work. (*b*) Chemistry and Physics in relation to public health, during 90 hours, of which not less than 70 hours have been occupied in practical laboratory work. (*c*) Meteorology and Climatology in relation to public health, during not less than 10 hours.

Candidates will be admitted to Part II. of the Examination on producing evidence :—

1. Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less than two years, of being registered by the General Medical Council, and of having completed the curriculum for the Diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification.

2. Of having attended, after obtaining the registrable Qualification, instruction during not less than 80 hours at an Institution recognised by the Examining Board in England in the following subjects :—(*a*) The Principles of Public Health and Sanitation for not less than 30 hours; (*b*) Epidemiology and Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours; (*d*) Sanitary Construction and Planning during not less than 10 hours.

3. Of having attended for three months the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England and of having therein received instruction in the methods of administration. This course must include 30 daily attendances of not less than two hours in each week.

4. Of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a Medical Officer of Health, and of having received, from such officer or other competent Medical Officer during not less than three hours on each of 60 working days, practical instruction in those duties and also those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for children of school age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk.

The above certificate (4) must be obtained from a Medical Officer of Health who devotes his whole time to public work, or from a Medical Officer of Health of a Sanitary Area having a population of not less than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

University of Oxford.—An examination, conducted partly in writing, partly vivâ voce, and in each subject partly practical, is held in Michaelmas and in Trinity Term in the following subjects :—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £10 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise (*a*) written papers of three hours each in (i.) Chemistry and Physics, and (ii.) Pathology and Bacteriology; (*b*) a three hours' practical and vivâ voce examination in Chemistry and Physics; (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

The Second Part of the Examination will consist of the following parts :—(*a*) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health); (*b*) a practical and vivâ voce examination in General Hygiene; and (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce certificates (1) of Laboratory Work in Chemistry as applied to Hygiene, and (2) of having had Practical Instruction in Bacteriology, and the Pathology of the Diseases of Animals transmissible to Man.

Candidates in Part II. will produce the following further certificates: (3) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration.

All the above degrees are now open to Women Students, and particulars of Scholarships, &c., may be obtained from the Principals of the various Ladies' Colleges. The names of candidates for the Diploma in Public Health must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford. Applications for any further information should be addressed to the Dean, Department of Medicine, Museum, Oxford.

University of Cambridge.—Two examinations in so much of State medicine as is comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) Part I. of the examination; or (2) Part II. of the examination. Every candidate will be required to pay a fee of £10 10*s*. before admission or readmission to *either part* of the examination. Candidates must before admission to either part of the examination produce evidence of having satisfied the regulations applicable to Part I. and Part II.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University on Hygiene, Chemistry, &c., and on Bacteriology and Parasitology. For Part II. the Medical Officer of Health for Cambridge gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital, and the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology. There are also special courses in Vital Statistics, Tuberculosis Service, Venereal Diseases Service, Industrial Hygiene, Maternity and Child Welfare. These courses are open to non-members of the University.

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England.

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.—Candidates for the M.D. degree may offer State medicine as a subject in which to graduate. They must send to the Academic

Registrar with their forms of entry certificates (i.) of having, subsequently to having obtained a registrable qualification to practise Medicine, attended a course of practical instruction in a laboratory or laboratories, British or foreign, approved by the University, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught; such course to extend over a period of not less than six months and to consist of at least 240 hours, of which not more than one-half shall be devoted to practical chemistry. (ii.) *Either* of having, subsequently to having obtained a registrable qualification to practise Medicine, during six months (of which at least three months shall be distinct and separate from the above-mentioned period of laboratory instruction) been diligently engaged on not less than 60 working days in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a person recognised by the University as entitled to grant certificates. *Or* of having held for a period of not less than three years an appointment as Medical Officer of Health of a Sanitary District within the British Dominions, and having a population of not less than 15,000. (iii.) Of having, subsequently to having obtained a registrable qualification to practise Medicine, attended at least twice weekly during a period of not less than three months a practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. In connexion with this degree the various metropolitan medical schools hold regular classes under teachers of Public Health and Sanitary Science, such instruction being also used to obtain the various diplomas of other Universities and of those Royal Corporations which grant them.

University of Durham.—The Degree of Bachelor of Hygiene (B.Hy.) and the Diploma in Public Health (D.P.H.).—No candidate is admitted to the final examination for the Degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University, and no candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner, of not less than two years' standing. The course of study for the B.Hy. and D.P.H. extends over a period of not less than 12 calendar months, subsequent to the attainment of a registrable qualification. Candidates for the B.Hy. must attend this course at the University of Durham; candidates for the D.P.H. may attend it at the University of Durham, or at any medical school or institution which is recognised by the University. The examination for the diploma or degree is divided into two parts. A candidate must pass in all the subjects of Part I. before being admitted to examination for Part II. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. The examination for Part I. is practical, written, and oral, and includes the following subjects: Bacteriology and Parasitology (including medical entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. Candidates are not admitted to examination for Part I. until after they have completed the prescribed courses of instruction in the subjects thereof. The examination for Part II. includes Hygiene and Sanitation (including sanitary construction), Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination is written and oral, and includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—Dwellings, Factories, Workshops, Schools, &c. Candidates are not admitted to examination for Part II. until after they have completed the prescribed courses of instruction in the subjects thereof.

The fee for the examination for the degree of B.Hy. is £10 10*s*. and for the degree £6 6*s*. Candidates for the degree of Doctor of Hygiene (D.Hy.) shall be Bachelors of Hygiene of two years' standing, and shall be required to satisfy the examiners that they have conducted original research in the subject of Public Health. The fee for the examination for the degree of D.Hy. is £20 and for the degree £10. The fee for the examination for the Diploma in Public Health is £10 10*s*. and for the diploma £3.

Victoria University of Manchester.—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part of the examination is £8 8*s*., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £4 4*s*. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examination will begin about the middle of July and the middle of October in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice. An examination for a Diploma in Bacteriology is held for graduates in science or medicine who have attended prescribed courses for at least one academic year; candidates must present a satisfactory thesis on an approved subject.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £6 5*s*. Medical Officers of the Royal Navy who have attended courses in Hygienic Chemistry, Bacteriology, and Public Health at the Naval Medical School, Greenwich, will be admitted to the examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the Staff College and pursued the further course of study approved by the General Medical Council.

University of Liverpool.—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The courses may be taken out at any time, and students are allowed to work daily in the laboratories. Composition fee for M.H. £40 a session, and D.P.H. £45 a course.

University of Leeds.—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates must pass in Part I. before being admitted to Part II. Fees.—The fee for each part is £8 6*s*., and for any subsequent examination in the same part £4 4*s*. Instruction in Entomology and Meteorology given in the first term, and in Sanitary Chemistry nd Bacteriology in the second and third terms. ractical work under arrangement with the Leeds ity Council. Prospectus can be obtained from the cademic Sub-Dean of the Medical School.

University of Bristol.—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than two years' standing as such, and shall have passed the examination prescribed by regulation. The examination is divided into two parts.

University of Wales.—Candidates for the Diploma in Public Health, the curriculum for which extends over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification, must produce evidence of having attended for not less than five months at the Welsh National School of Medicine or at an institution approved by the Court, practical instruction in Bacteriology and Parasitology, Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates must also satisfy the examiners that they have received instruction approved by the University in the Principles of Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. The candidate must also produce evidence that he has attended for three months on the clinical practice of a hospital for infectious diseases containing not less than 100 beds, and has received therein instruction in the methods of administration, and that he has for a period of not less than six months been engaged in acquiring a practical knowledge of the duties, routine and special, of a public health administration under the supervision of a medical officer of health. The examination for the diploma is divided into two parts, Part I. and Part II., each of which extends over not less than two days. A candidate must pass in all the subjects of Part I. before being admitted to Part II. of the examination. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. Part I. of the examination is practical, written and oral, and includes Bacteriology and Parasitology (including Medical Entomology); Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates may not be admitted to Part I. of the examination until they have been certified as having pursued the prescribed courses of instruction in the subjects thereof. Part II. of the examination, which is written and oral, includes: Hygiene and Sanitation (including Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. No candidate can be admitted to Part II. of the examination until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered before admission to Part II. of the examination. An examination in each part will be held annually, in June. Notice of candidature, together with the fee of six guineas for either part of the examination, must be sent to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 15th.

University of Edinburgh.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. A Diploma in Tropical Medicine and Hygiene is also granted. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £4 4*s.* for the First and £5 5*s.* for the Second B.Sc. Examinations, and £15 15*s.* for the degree of D.Sc.

University of Aberdeen.—Every candidate for the Diploma in Public Health must be a graduate in medicine of the University of Aberdeen, or of any other University whose medical degrees are recognised as qualifying for registration by the General Medical Council of the United Kingdom. No candidate will be admitted to the Final Part of the Examination for the Diploma until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, which qualification shall have been registered before such admission. The whole of the prescribed curriculum of study must be undertaken after the candidate has obtained a registrable qualification in medicine, and shall extend over not less than twelve calendar months. At least one academic term must be spent at the University of Aberdeen. Every candidate shall produce evidence of having complied with the following requirements in respect of study and training:—1. Practical instruction in the following subjects within a laboratory or laboratories approved by the University: (*a*) Bacteriology and Parasitology (including Medical Entomology), in relation to diseases of man and diseases of lower animals transmissible to man—at least 180 hours, of which not less than 150 shall be occupied in practical laboratory work; (*b*) Chemistry and Physics, in relation to Public Health—at least 90 hours, of which not less than 70 shall be occupied in practical laboratory work; (*c*) Meteorology and Climatology, in relation to Public Health—at least 10 hours; such instruction to extend over not less than five months or two academic terms. 2. A course or courses of instruction extending over not less than 80 hours dealing with: (*a*) The Principles of Public Health and Sanitation—30 hours; (*b*) Epidemiology and Vital Statistics—20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services)—20 hours; (*d*) Sanitary Construction and Planning—10 hours; such course or courses to be given at an institution or by a teacher or teachers approved by the University. 3. Practical instruction, clinical and administrative, within a recognised hospital for general infectious diseases: such instruction to extend over three months, and to include 30 daily attendances of not less than two hours in each week. 4. Practical instruction and experience, during not less than six months (including attendance of at least three hours on each of sixty working days) in the duties, routine and special, of public health administration, under the supervision of a medical officer of health, who shall certify that the candidate has received from this officer or other competent medical officer, practical instruction in these duties, and also in those relating to:—(*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The medical officers of health recognised for this purpose by the General Medical Council are: (*a*) a medical officer of health who devotes his whole time to public health work; or (*b*) the medical officer of health of a sanitary area having a population of not less than 50,000; or (*c*) in Ireland, the medical superintendent officer of health of a county or county borough having a population of not less than 50,000. The examination for the diploma is divided into two parts, each of which extends over not less than three days. The following are the fees payable for the courses of instruction given within the University: Lecture Course or Courses, £4 4*s.*; Laboratory Instruction, £14. The examination fee is £8 8*s.*, which is payable as follows:—£4 4*s.* for Part I., and £4 4*s.* for Part II. The fees for external instruction amount approximately to £11 11*s.*

University of Glasgow.—Degree of B.Sc. in Public Health.—Candidates must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose by the University Court. Candidates must produce evidence (1) that, after they have obtained a registrable Degree in Medicine, a period of not less than two years has elapsed; (2) that, after they have obtained a registrable degree in Medicine, they have, during a period of not less than 21 calendar months, pursued the course of work and instruction prescribed, and have satisfied the examiners in the prescribed examinations. There are two examinations. Part I. includes the following subjects: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health; (iv) Higher Chemistry in relation to Public Health; (v) Physics and Geology. A candidate must pass in the subjects marked (i), (ii), and (iii) of Part I. at one examination. Part II. includes the following subjects: (vi) Hygiene and Sanitation (including Sanitary construction); (vii) Epidemiology and Infectious Diseases; (viii) Sanitary Law and Vital Statistics; (ix) Public Health Administration; (x) Applied Hygiene. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene shall be on the selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.).*—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written and oral, is divided into two parts, Part I. and Part II., each of which extends over not less than two days. No candidate is admitted to either part of the examination until he has completed the prescribed courses of instruction in the subjects of that part. No candidate is admitted to Part II. until he has passed in all the subjects of Part I., nor until after the lapse of not less than two years from the date of his obtaining a registrable medical qualification, nor unless he presents a certificate showing that his name and qualification have been duly registered in the Medical Register. Part I. includes: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health. A candidate must pass in all the subjects at one examination. Part II. includes: (iv) Hygiene and Sanitation (including Sanitary Construction); (v) Epidemiology and Infectious Diseases; (vi) Sanitary Law and Vital Statistics; (vii) Public Health Administration. A candidate must pass in all the subjects at one examination. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like.

University of St. Andrews.—The Diploma in Public Health is open to medical graduates of a University of the United Kingdom. The examination is in two parts. (1) (*a*) Bacteriology and Parasitology; (*b*) Chemistry and Physics; (*c*) Meteorology and Climatology. (2) Hygiene and Sanitation, Epidemiology and Infectious Diseases, Sanitary Law and Vital Statistics, Public Health Administration. Before admission to the first examination the candidate must have held his medical degree for one year, and before admission to the second examination for two years. Graduates in Medicine of the University of St. Andrews may take part of all of the qualifying classes in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised by the University Court, but graduates of another University must spend at least eight out of the 12 months' curriculum in St. Andrews University. A complete course is given in United College, Dundee. The examination fee for each division is £5 5*s.*

University of Dublin (Trinity College).—The Diploma in Public Health is conferred, after examination, under the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least two years before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, five months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have received instruction in the following subjects: The principles of public health and sanitation; epidemiology and vital statistics; sanitary law and administration (including public medical services); sanitary construction and planning, must have studied, practically, outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

*National University of Ireland.**—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

---

* No returns.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held in two parts, in March and in June. The first part of the examination will have reference to the general principles of sanitary science and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 1 guinea.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Bacteriology in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer; and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics and Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination, *and intimation is made that the curriculum and examination will be adjusted to meet the requirements of the regulations of the General Medical Council which came into force on Jan. 1st, 1924.* Candidates applying for Regulations should state date of commencement of curriculum. The Registrar for Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and for Glasgow Mr. Walter Hurst, 242, St. Vincent-street.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.—Every candidate for the Diploma in Public Health must observe the following rules: 1. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the Final Examination for a Diploma in Public Health. 2. The curriculum for a Diploma in Public Health shall extend over a period of not less than 12 calendar months subsequent to the attainment of a registrable qualification. 3. Every candidate shall produce evidence of having attended, during a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, practical instruction in—(*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; (*b*) Chemistry and Physics in relation to Public Health; (*c*) Meteorology and Climatology in relation to Public Health. At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be occupied in practical Laboratory work. At least 90 hours must be devoted to Course (*b*), of which not less than 70 hours shall be occupied in practical Laboratory work. At least 10 hours must be devoted to Course (*c*). 4. Evidence of having received, during not less than 80 hours, at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects: (*a*) The Principles of Public Health and Sanitation; (*b*) Epidemiology and Vital Statistics; (*c*) Sanitary Law and Administration (including Public Medical Services); (*d*) Sanitary Construction and Planning. 5. Evidence that he has attended for three months on the clinical practice of a recognised Hospital for Infectious Diseases. 6. Evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health. The examination for the Diploma is divided into two parts. The examination for Part I. includes Bacteriology and Parasitology (with Medical Entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. The examination for Part II. includes Hygiene and Sanitation (with Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination, which is written and oral, includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises—dwellings, factories, workshops, schools, &c.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available.

THE DENTAL BOARD OF THE UNITED KINGDOM.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly-constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts.

The Dental Board consists of a chairman and 12 members. The term of office of the first Board, appointed in December, 1921, ended on July 28th last, and the new Board awaits appointment. The following are the names and sources of appointment of the retiring members: Chairman of the Board: Rt. Hon. F. Dyke Acland, appointed by the Privy Council. Members of the Board: Mr. L. G. Brock, Mr. W. H. Dolamore, M.R.C.S., L.D.S., and Mr. W. H. Gilmour, M.R.C.S., L.D.S., appointed by the Minister of Health; Mr. D. M'Coig Cowan, M.P., and Mr. William Guy, F.R.C.S.E., L.D.S., appointed by the Scottish

Board of Health; Mr. James H. Stirling and Mr. Edward L. Sheridan, F.R.C.S.I., L.D.S., appointed by the Lord Lieutenant of Ireland; Mr. H. J. Waring, Sir James Hodsdon, and Sir Arthur Chance, appointed by the General Medical Council; Mr. Fred Butterfield and Mr. H. A. Robertshaw, appointed by the Privy Council. Treasurers of the Board: Mr. H. J. Waring and Mr. W. H. Dolamore.

The offices of the Board are at 44, Hallam-street, London, W. 1, adjoining the offices of the General Medical Council.

Registration of Dental Students.

The following are the General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923.

The Council recommends that, subject to such exceptions as the Council may from time to time allow, every dental student at the commencement of his studentship should be registered in the manner and under the conditions hereinafter set forth.

1. The registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and is subject to the same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence by pupilage with a registered dental practitioner.

2. Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in mechanical dentistry (see No. 3 below).

3. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school.

4. Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study.

5. The necessary instruction in dental mechanics, or any part of it, may be taken by the dental student either before or after his registration as a student. When a student can show evidence of regular pupilage in dental mechanics to a registered practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations (see No. 3 above).

Examining Bodies in Dentistry.

The following is a list of the Examining Bodies in Dentistry which grant diplomas or degrees in this subject. The regulations for obtaining these qualifications will appear in a guide to teaching institutions in dentistry at a later date.

Royal College of Surgeons of England.—Diploma in Dental Surgery.

Royal College of Surgeons, Edinburgh.—Licence in Dental Surgery. The College also grants a higher dental diploma which is registrable in the Dentists Register as an additional qualification.

Royal Faculty of Physicians and Surgeons of Glasgow.—Licence in Dental Surgery. The curriculum, which is similar to that of Edinburgh, includes in addition dental bacteriology.

Royal College of Surgeons in Ireland.—Licence in Dental Surgery.

University of Birmingham.—Dental diploma; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

University of Bristol.—Diploma in Dental Surgery; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

University of Durham.—Licence in Dental Surgery; degrees of Bachelor of Dental Surgery (B.D.S.) and of Master of Dental Surgery (M.D.S.).

University of Leeds.—Diploma in Dental Surgery; degrees of Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.).

University of Liverpool.—Licence in Dental Surgery; (L.D.S.); degrees in Dental Surgery (B.D.S. and M.D.S.).

University of London.—Degree of Bachelor of Dental Surgery.

University of Manchester.—Degrees of B.D.S.; and a diploma in Dentistry.

University of Sheffield.—Degree of Bachelor of Dental Surgery; and the diploma of Licentiate in Dental Surgery.

Queen's University of Belfast.—Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery.

Teaching Institutions in Dentistry.

In addition to facilities provided by the above Universities, Colleges, and Faculties, a number of dental courses are available. In London at the Royal Dental Hospital (School of Dental Surgery), Leicester-square, at University College Hospital Dental School, and at the Dental Departments of Guy's Hospital and of the London Hospital. In the provinces at the Birmingham, Manchester, and Newcastle-on-Tyne dental hospitals. In Scotland at the Incorporated Edinburgh Dental Hospital, the Incorporated Glasgow Dental Hospital, and the Dental Department of Glasgow Royal Infirmary. In Ireland at the Incorporated Dental Hospital of Ireland, Dublin. Dental study may be commenced also at any of the following schools: Birmingham Dental Hospital, Bristol Royal Infirmary and General Hospital, Dundee Dental Hospital, Leeds Dental Hospital, Liverpool Dental Hospital, and Sheffield Royal Hospital.

The Services.

ROYAL ARMY MEDICAL CORPS.

A. E. Campbell, G. C. Phipps, K. Lumsden, J. R. A. Madgwick, and F. H. King to be Lts. on probation.

ARMY RESERVE OF OFFICERS.

Lt.-Col. and Bt. Col. C. B. Lawson, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. A. C. Goodwin, having attained the age limit, is retd., and is granted the rank of Lt.-Col. with permission to wear the prescribed uniform.

Medical News.

University of London Graduates' Association. This Association is supporting the candidature of E. G. Graham Little, M.D., F.R.C.P. Lond., in the University by-election. Dr. Little has represented the medical graduates of Convocation on the Senate continuously since 1906, and is chairman of the Council for External Students.

There is a proposal for an International Congress of Radiology to be held in London at the end of June, 1925. Secretaries of radiological societies in each country are being asked to form organising committees and to send suggestions for the programme of proceedings. The provisional committee charged with the preliminary arrangements will meet in London early in September; its members include Dr. G. W. C. Kaye, Dr. Robert Knox, Dr. Stanley Melville, Dr. E. A. Owen, Dr. Russell J. Reynolds, Dr. R. W. A. Salmond, Dr. F. Shillington Scales, Dr. S. Gilbert Scott, Dr. Walter J. Turrell, and Drs. J. E. A. Lynham and John Muir, joint secretaries. All communications should be addressed to the Secretary, International Congress of Radiology, care of the British Institute of Radiology, 32, Welbeck-street, London, W. 1.

The Brackenbury Testimonial Fund.—All contributions should be in the hands of the hon. secretaries, Dr. Harold S. Beadles and Dr. Peter Macdonald, 429, Strand, London, W.C., by August 31st at the latest. It has been decided that the presentation will be made on the evening of Oct. 15th.

Post-Graduate Medical Study in Paris.—A post-graduate course will be held at the Clinique Médicale de l'Hôtel Dieu, commencing on Sept. 15th, dealing with recent medico-chirurgical views on diseases of the alimentary canal. The course is under the direction of Prof. A. Gilbert, assisted by Prof. Maurice Villaret, and will consist of 36 meetings spread over a period of two weeks. The fee for the course is 150 francs. Further particulars and full programme may be obtained from Prof. Gilbert, at the Faculté de Médecine, Université de Paris.

Post-Graduate Medical Study in Vienna.—The fourteenth and fifteenth international post-graduate courses in medicine at the Medical Faculty of Vienna will be held respectively from Sept. 29th to Oct. 11th, and from Nov. 24th to Dec. 6th. The first course will deal with the most important medical questions of the day, with special reference to therapeutics for the practitioner, and the second course will deal with children's diseases. A full programme of these courses and information regarding further opportunities of post-graduate study at Vienna may be obtained from the Dean of the Vienna Medical Faculty, Prof. Alfred Fischel, at the University, Ring des 12. November, Vienna I.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Sept. 1st, to Saturday, Sept. 6th.—Hospital for Diseases of the Skin, Blackfriars.—Instruction in the Out-patient Department every afternoon from 2.30 p.m. Venereal Clinic, Tuesday and Friday, from 5.30 to 7 p.m. West End Hospital for Nervous Diseases.—Each day at 5 p.m. Mon., Dr. Hildred Carlill: Tabes Dorsalis. Tues., Mr. Laming Evans: Orthopædic Treatment in Diseases of Nervous System. Wed., Mr. Lindsay Rea: The Examination of the Eye in Nervous Diseases. Thurs., Dr. Ridley Prentice: Hemiplegia and Monoplegia. Fri., Dr. Worster-Drought: Investigation of Cranial Nerve Disorders.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Sept. 1st.—11 a.m., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 p.m., Dr. Scott Pinchin: Medical Out-patients.

Tuesday.—12 noon, Dr. Burrell: Chest Cases. 2 p.m., Mr. Sinclair: Surgical Out-patients. 2.30 p.m., Mr. Tyrrell Gray: Surgical Wards.

Wednesday.—11 a.m., Medical Registrar: Medical Wards. 2 p.m., Dr. Pernet: Skin Department. 2.30 p.m., Mr. Donald Armour: Surgical Wards.

Thursday.—10 a.m., Dr. Grainger Stewart: Neurological Department. 2 p.m., Mr. MacDonald: Genito-Urinary Department. 2 p.m., Mr. Bishop Harman: Eye Department.

Friday.—10 a.m., Mr. Dudley Buxton: Dental Department. 11 a.m., Dr. McDougal: Electrical Department. 2 p.m., Mr. Vlasto: Throat, Nose, and Ear Department.

Saturday.—9.30 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Medical Diseases of Children. 10 a.m., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

Appointments.

Allan, Ernest, M.B., Ch.B. Edin., has been appointed Ophthalmic Surgeon to the Stanley Hospital, Liverpool.

Jardine, J., M.D. Edin., F.R.C.S. Edin., Medical Officer and Inspector of Physical Training for the Scottish Educational Department.

Murdoch, Georgina, M.B., Ch.B. Glasg., Medical Officer of Health for Oldham.

St. Thomas's Hospital: Cooke, A. M., M.B., B.Ch. Oxf., Turney, H. F., M.B., B.Ch. Oxf., Walker, E. L. G., M.R.C.S., L.R.C.P. Lond., McLean, W. W., M.R.C.S., L.R.C.P. Lond., Thwaites, W. G., M.R.C.S., L.R.C.P. Lond., Gervis, W. H., M.R.C.S., L.R.C.P. Lond., Hudson, M. W. P., M.R.C.S., L.R.C.P. Lond., and Starkey, R. S., M.R.C.S., L.R.C.P. Lond., Casualty Officers and Resident Anæsthetists; Hope-Simpson, J. W., M.B., B.Ch. Camb., Yates, H., M.R.C.S., L.R.C.P. Lond., Creed, R. S., M.B., B.Ch. Oxf., and Berridge, W. C. M., M.R.C.S., L.R.C.P. Lond., Resident House Physicians; Briggs, T. F., M.R.C.S., L.R.C.P. Lond., Resident House Physician for Children; Jeffery, A. L. P., M.B., B.S. Lond., Walford, A. S. H., M.B., B.Ch. Camb., Webb-Peploe, M. H., M.B., B.Ch. Camb., Metcalfe, G. A., M.B., B.Ch. Camb., Resident House Surgeons; Allan, F. G., M.R.C.S., L.R.C.P. Lond., Resident Orthopædic House Surgeon; Rees, E. J., M.R.C.S., L.R.C.P. Lond., Resident House Surgeon (Ear); Davies, D. V., M.R.C.S., L.R.C.P. Lond., Resident House Surgeon (Throat); Chadwick, S. A. R., M.R.C.S., L.R.C.P. Lond., Senior Obstetric House Physician; Weaver-Adams, E. R., M.R.C.S., L.R.C.P. Lond., Junior Obstetric House Physician; Jones, H. V. M., M.B., B.S. Lond., Senior Ophthalmic House Surgeon; Penman, G. G., M.B., B.Ch. Camb., Junior Ophthalmic House Surgeon; Neilson, D. F. A., F.R.C.S. Eng., Cavenagh, J. B., M.B., B.Ch. Oxf., Doyle, A. F., M.R.C.S., L.R.C.P. Lond., Oliver, J. O., M.R.C.S., L.R.C.P. Lond., Barron, R. T., M.D. Lond., Facey, R. V., M.B., B.Ch. Oxf., Marsh, R. G. B., M.R.C.S., L.R.C.P. Lond., Marriner, H. L., F.R.C.S. Edin., Armanious, F. H., M.R.C.S., L.R.C.P. Lond., Lloyd-Williams, P., M.R.C.S., L.R.C.P. Lond., L.D.S., Archer, E. C., M.R.C.S., L.R.C.P. Lond., Sims, T. H., M.R.C.S., L.R.C.P. Lond., Thompson, W. D. R., M.R.C.S., L.R.C.P. Lond., Watkins-Pitchford, H. O., M.R.C.S., L.R.C.P. Lond., Wrigley, A. J., M.R.C.S., L.R.C.P. Lond., Rea, R. H. T., M.R.C.S., L.R.C.P. Lond., Thompson, J. H. G., M.R.C.S., L.R.C.P. Lond., Barrett, J. C., F.C., M.R.C.S., L.R.C.P. Lond., Pilot, R., M.R.C.S., L.R.C.P. Lond., Evans, T. L., M.R.C.S., L.R.C.P. Lond., Doyle, A. F., M.R.C.S., L.R.C.P. Lond., McKaig, G. A., M.R.C.S., L.R.C.P. Lond., Rickman, J., M.B., B.Ch. Camb., and Bauwens, P., M.R.C.S., L.R.C.P. Lond., Assistants.

Vacancies.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Milborne Port, Somerset.

A vacancy is announced under the Workmen's Compensation Acts for a Medical Referee for the County of Antrim and the County of the City of Belfast. Forms of application and scales of fees payable may be obtained from the Secretary, Ministry of Labour, 7, Upper Queen-street, Belfast.

Births, Marriages, and Deaths.

BIRTHS.

Boswell.—On August 13th, at Southborough-road, Bickley, Kent, the wife of Philip R. Boswell, M.C., M.B., B.Ch. Camb., of a son.

Bracewell.—On August 16th, at Wrentham House, Wrentham, Lowestoft, the wife of Charles H. Bracewell, M.R.C.S., L.R.C.P., of a daughter.

Peebles.—At Salterley Grange, Cheltenham, on August 20th, to Dr. and Mrs. D. J. Peebles, a daughter.

Scott.—On August 16th, at Old Market-street, Bristol, the wife of Dr. H. Hope Scott, of a son.

Woodman.—On August 21st, at 132, Hagley-road, Edgbaston, the wife of E. Musgrave Woodman, M.S., F.R.C.S., of a daughter.

MARRIAGES.

Buchanan—Godsal.—On August 14th, at the Parish Church, Hurst, Berks, John Vessie Buchanan, M.B., Ch.B., of Shaw, Lancs, to Marion Waiata, younger daughter of Edward Hugh Godsal, Great Mead, Wokingham.

Nixon—Walker.—On August 18th, at S. Crantoc, Newquay, Cornwall, John Alexander Nixon, C.M.G., M.D., F.R.C.P., to Doreen Gennifer Constantia Walker, M.R.C.S., L.R.C.P.

Smith—Thomas.—On August 2nd, at St. Mary's, Hanwell, Ernest Flavel Smith, M.B., B.S. Lond., to Neryl Eleanor Mary Thomas, only daughter of Mr. and Mrs. O. B. Thomas, of "Homeleigh," Oaklands-road, Hanwell.

DEATHS.

Burridge.—On August 17th, at a nursing home, Henry Alfred Burridge, B.A., M.B., &c., of 15, Cambalt-road, Putney, aged 57 years.

Lascelles.—On August 16th, at his residence, "Caulfield," Earlestown, Lancs, suddenly, of heart failure, John Lascelles, M.B., B.Ch., B.A.O., aged 32 years. Buried at Downpatrick August 19th, 1924.

McFarlane.—On August 17th, at King's College Hospital, Dr. F. Norman McFarlane, M.B. Edin., late of the Radcliffe Infirmary, Oxford, aged 28 years.

Pattison.—On August 21st, at Charing Cross Hospital, after a long illness, Edward Seton Pattison, L.R.C.P. Lond., M.R.C.S. Eng., in his sixty-ninth year.

Smith.—On August 16th, at Bournemouth, the result of accident, James William Smith, L.R.C.P. Lond., M.R.C.S., late of Doncaster, aged 83.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Board of Health; Mr. James H. Stirling and Mr. Edward L. Sheridan, F.R.C.S.I., L.D.S., appointed by the Lord Lieutenant of Ireland; Mr. H. J. Waring, Sir James Hodsdon, and Sir Arthur Chance, appointed by the General Medical Council; Mr. Fred Butterfield and Mr. H. A. Robertshaw, appointed by the Privy Council. Treasurers of the Board: Mr. H. J. Waring and Mr. W. H. Dolamore.

The offices of the Board are at 44, Hallam-street, London, W. 1, adjoining the offices of the General Medical Council.

REGISTRATION OF DENTAL STUDENTS.

The following are the General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923.

The Council recommends that, subject to such exceptions as the Council may from time to time allow, every dental student at the commencement of his studentship should be registered in the manner and under the conditions hereinafter set forth.

1. The registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and is subject to the same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence by pupilage with a registered dental practitioner.

2. Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in mechanical dentistry (see No. 3 below).

3. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school.

4. Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study.

5. The necessary instruction in dental mechanics, or any part of it, may be taken by the dental student either before or after his registration as a student. When a student can show evidence of regular pupilage in dental mechanics to a registered practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations (see No. 3 above).

EXAMINING BODIES IN DENTISTRY.

The following is a list of the Examining Bodies in Dentistry which grant diplomas or degrees in this subject. The regulations for obtaining these qualifications will appear in a guide to teaching institutions in dentistry at a later date.

Royal College of Surgeons of England.—Diploma in Dental Surgery.

Royal College of Surgeons, Edinburgh.—Licence in Dental Surgery. The College also grants a higher dental diploma which is registrable in the Dentists Register as an additional qualification.

Royal Faculty of Physicians and Surgeons of Glasgow.—Licence in Dental Surgery. The curriculum, which is similar to that of Edinburgh, includes in addition dental bacteriology.

Royal College of Surgeons in Ireland.—Licence in Dental Surgery.

University of Birmingham.—Dental diploma; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

University of Bristol.—Diploma in Dental Surgery; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

University of Durham.—Licence in Dental Surgery; degrees of Bachelor of Dental Surgery (B.D.S.) and of Master of Dental Surgery (M.D.S.).

University of Leeds.—Diploma in Dental Surgery; degrees of Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.).

University of Liverpool.—Licence in Dental Surgery; (L.D.S.); degrees in Dental Surgery (B.D.S. and M.D.S.).

University of London.—Degree of Bachelor of Dental Surgery.

University of Manchester.—Degrees of B.D.S.; and a diploma in Dentistry.

University of Sheffield.—Degree of Bachelor of Dental Surgery; and the diploma of Licentiate in Dental Surgery.

Queen's University of Belfast.—Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery.

TEACHING INSTITUTIONS IN DENTISTRY.

In addition to facilities provided by the above Universities, Colleges, and Faculties, a number of dental courses are available. In London at the Royal Dental Hospital (School of Dental Surgery), Leicester-square, at University College Hospital Dental School, and at the Dental Departments of Guy's Hospital and of the London Hospital. In the provinces at the Birmingham, Manchester, and Newcastle-on-Tyne dental hospitals. In Scotland at the Incorporated Edinburgh Dental Hospital, the Incorporated Glasgow Dental Hospital, and the Dental Department of Glasgow Royal Infirmary. In Ireland at the Incorporated Dental Hospital of Ireland, Dublin. Dental study may be commenced also at any of the following schools: Birmingham Dental Hospital, Bristol Royal Infirmary and General Hospital, Dundee Dental Hospital, Leeds Dental Hospital, Liverpool Dental Hospital, and Sheffield Royal Hospital.

The Services.

ROYAL ARMY MEDICAL CORPS.

A. E. Campbell, G. C. Phipps, K. Lumsden, J. R. A. Madgwick, and F. H. King to be Lts. on probation.

ARMY RESERVE OF OFFICERS.

Lt.-Col. and Bt. Col. C. B. Lawson, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. A. C. Goodwin, having attained the age limit, is retd., and is granted the rank of Lt.-Col. with permission to wear the prescribed uniform.

Medical News.

UNIVERSITY OF LONDON GRADUATES' ASSOCIATION.—This Association is supporting the candidature of E. G. Graham Little, M.D., F.R.C.P. Lond., in the University by-election. Dr. Little has represented the medical graduates of Convocation on the Senate continuously since 1906, and is chairman of the Council for External Students.

THERE is a proposal for an International Congress of Radiology to be held in London at the end of June, 1925. Secretaries of radiological societies in each country are being asked to form organising committees and to send suggestions for the programme of proceedings. The provisional committee charged with the preliminary arrangements will meet in London early in September; its members include Dr. G. W. C. Kaye, Dr. Robert Knox, Dr. Stanley Melville, Dr. E. A. Owen, Dr. Russell J. Reynolds, Dr. R. W. A. Salmond, Dr. F. Shillington Scales, Dr. S. Gilbert Scott, Dr. Walter J. Turrell, and Drs. J. E. A. Lynham and John Muir, joint secretaries. All communications should be addressed to the Secretary, International Congress of Radiology, care of the British Institute of Radiology, 32, Welbeck-street, London, W. 1.

An Address
ON THE
DIAGNOSIS OF A HEALTHY HEART.

Delivered before the Canadian Medical Association at the Annual Meeting, Ottawa, on June 19th, 1924,

BY JOHN PARKINSON, M.D., F.R.C.P.LOND.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL AND PHYSICIAN-IN-CHARGE OF THE CARDIOGRAPHIC DEPARTMENT; PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

THE purpose of this address is to deal with the recognition of a healthy heart when circumstances arise which impugn its integrity. The soundness of the doctrine that diagnosis is the basis of good treatment is nowhere better exemplified than in heart disease, so that the duty is clearly imposed on us to decide first of all whether heart disease is or is not present. The general feeling of a public ignorant of the modern trend of preventive medicine is that doctors are primarily concerned with disease; but though it is our privileged misfortune to deal with disease most of our time, this should not close our eyes to the recognition of a healthy organ when its functions are merely deranged, or when other members of the corporate body cast on it clinical aspersions which are undeserved. Not only from the standpoint of rational treatment would I emphasise the prime importance of this diagnosis of a healthy heart whenever it is honestly possible, but from that of the general interests of the patient in allaying his fears and restoring his confidence. I would urge that in no branch of medicine is it more desirable to cultivate the art of deciding when disease is absent and apprehension baseless.

The responsibility of diagnosing a healthy heart should not be shirked because of the professional risk we incur of giving a good prognosis in error; and we should not seek to avoid that risk by adopting an attitude of pessimistic complacence which allows us to diagnose heart disease on mere suspicion, or to accept a second-hand diagnosis which may be brought us when, in fact, the heart may be sound. Such an attitude of playing for safety would be more justifiable were our heart cases doomed to end with the dramatic abruptness usually depicted by the novelist and imagined by the laity; a belief which is false, and founded, not on general experience, but on the distorting impression of an occasional casualty. The progress of cardiac disease as a rule gives us ample time for a revision of our prognosis. Moreover, serious heart disease is recognisable and is recognised in practice. It is rarely that a grievous malady of the heart is so elusive as to be missed, unless it be angina pectoris (which error might happen to the most experienced of us); and though a damaged heart may bear a semblance of health in this and other conditions I shall hereafter discuss, it can with a measure of certainty be caught in the net of clinical investigation.

The tendency to excessive diagnosis of heart disease was rife in the war when thousands of men were rejected as unfit for service or were invalided out of the army on the slenderest evidence of valvular disease and a mistaken notion of the ambit of cardiac manifestations. The moral of many ex-Service men has been damaged to such an extent by this wrong diagnosis of heart disease that they will never again consider themselves fit to work. The same process of indiscriminate diagnosis of cardiac disease prevails in civil practice; or if the term disease is felt to be too strong or unpalatable to the patient, in its place is substituted a cryptic phrase familiar to us as a "weak heart" or a "strained heart." I would stress the fact that whatever the temptation to do otherwise, there is seldom any justification in the realm of heart trouble for other than a preliminary statement that either there is something wrong with the heart or there is not. Whenever we use the term "heart disease" it should imply something which will either shorten the life of our patient or restrict his activities. It might seem out of place for me to remind you that an exact diagnosis only will permit us to give the complete prognosis, and that it is a point of honour with the medical profession not to cause needless alarm in giving judgment. Surely, then, we would rather discover good grounds for an assurance that the heart is healthy, thereby allaying any apprehension a patient may reasonably have, than omit to sift the evidence which at first sight might be accepted as proof of disease and premature dissolution. It is therefore my wish to examine with you the evidence which may enable us to reduce this excessive diagnosis of heart disease by clarifying our conception of what really constitutes cardiac invalidism.

ÆTIOLOGY.

I will first consider the subject in the light of the ætiology of cardiac disease. During the last century it was customary to find in the text-books a long list of causes preceding the description of any particular cardiac disease. The list could always be described as being at least comprehensive! Just as progress in neurology has led to much simplification of the causes of nervous disease and the rejection of many conjectural causes—I need only mention tabes and syphilis as an example—so from diseases of the heart have untenable causes been dropped with the advance of precise and discerning knowledge. *Acute rheumatism* still holds its terrible position as the dominant cause of heart disease in children and young adults. This is the real "heart fever." The idea has been fostered that any infection may permanently injure the heart; and diphtheria, influenza, and scarlet fever are still viewed, I am afraid, as not infrequent offenders in this respect. These, it is true, are occasionally the cause of acute heart affections, but surely the risk of contracting a permanent valvular or myocardial disease from them is very remote. When, for instance, we meet with mitral stenosis or aortic incompetence in our young patient we do not think of scarlet fever or influenza, we think of rheumatism or chorea; and if we can find no history of candid rheumatism we try to elicit an account of some illness which to our medical minds spells rheumatism. It is worth the trouble to ask as a routine about St. Vitus's dance, for chorea in cardiac essence is rheumatism. I may add that rheumatism and its kindred should not lightly be dismissed from our minds even when no history of it can be obtained. For there is a likelihood that the brunt of a veiled attack may be borne by the heart—i.e., cardiac as distinct from articular rheumatism. A history of rheumatism or chorea should therefore always make us pause before diagnosing a healthy heart.

Syphilis is the other cause of infection and permanent, nay progressive disease of the heart—the cause which should loom in our minds when confronted with a patient developing heart disease in middle life. Morbid anatomy, supported by the discovery of the spirochæte and the Wassermann reaction, tells us that syphilitic *aortitis* is one of the commonest of post-mortem findings, so we cannot but admit its clinical frequency. It was an advance in medical science when saccular aneurysm was recognised as almost exclusively syphilitic: and the time has come for us to diagnose syphilitic aortitis and its other complications, aortic incompetence, and even angina pectoris. For aortic incompetence is generally syphilitic when it makes its appearance in middle life, and angina pectoris in middle life is most often a manifestation of syphilitic infection. In fact, if we could be sure that a person in youth or middle age had never been infected by *rheumatism* or by syphilis we might almost presume that he would possess a healthy heart.

Notes, Comments, and Abstracts.

THE STUDY AND PRACTICE OF MEDICINE.

THE ADVICE OF THREE OLD MASTERS—LATHAM, SYDENHAM, AND BRIGHT.

BY R. T. WILLIAMSON, M.D. LOND.,
CONSULTING PHYSICIAN TO THE ROYAL INFIRMARY, MANCHESTER.

IT has long been the custom for senior members of the profession to give advice on the study and practice of medicine by introductory lectures at our medical schools, or by articles in the medical journals at this season of the year, and in the medical literature of the past we have a large number of excellent addresses and articles on this subject; some are so excellent and so fitting to the unchanging spirit of the profession that they are worthy of recall. The words of three old masters of medicine of the past, P. M. Latham, Sydenham, and Bright, appear especially deserving of attention in our own time.

Peter Mere Latham, the distinguished physician to St. Bartholomew's Hospital, in an introductory lecture to medical students 90 years ago, gives his views of the spirit in which medical study and work should be conducted. After stating that the *diseased human body* will be the study and care of his hearers, he makes the following impressive remarks:—

"And is it possible to feel an interest in all this? Ay, indeed it is; a greater, far greater interest than ever painter or sculptor took in the form and beauties of its health. Whence comes this interest? At first, perhaps, it seldom comes naturally: a mere sense of duty must engender it; and still, for a while, a mere sense of duty must keep it alive. Presently the quick, curious, restless spirit of science enlivens it; and then it becomes an excitement and a pleasure, and then the deliberate choice of the mind. When the interest of attending the sick has reached this point, there arises from it, or has already arisen, a ready discernment of diseases, with a skill in the use of remedies. And the skill may exalt the interest, and the interest may improve the skill, until, in process of time, experience forms the consummate practitioner. But does the interest of attending the sick necessarily stop here? The question may seem strange. If it has led to the readiest discernment and the highest skill, and formed the consummate practitioner, why need it go further? But what if humanity shall warm it? Then this interest, this excitement, this intellectual pleasure, is exalted into a principle, and invested with a moral motive, and passes into the heart. What if it be carried still further? What if religion should animate it? Why, then, happy indeed is that man whose mind, whose moral nature, and whose spiritual being, are all harmoniously engaged in the daily business of his life; with whom the same act has become his own happiness, a dispensation of mercy to his fellow-creatures and a worship of God."

The advice of Latham is still worthy of careful consideration by all teachers and students of medicine, and by examiners. His warning respecting the limitation of the time devoted to clinical work, and his advice on the importance of the student being guided to observe for himself, were never more needed than to-day. Latham insisted on the importance of "self-teaching" by the student, and the danger of over-teaching on the part of the physician: he strongly advocated strict attention to work in the hospital wards, and urged the limitation of the number of lectures in medicine and surgery. He remarks: "I have always thought that, in our schools, every mode of lecturing has been unduly exalted above clinical lecturing; and every place where knowledge is to be had, or is supposed to be had, has been unduly preferred to the bedside; and I continue to think thus." Latham laments the lack of interest in treatment shown by so many physicians, who appeared to regard pathology and diagnosis of the greatest importance, but treatment as a humbler and less worthy part of their work. Of this attitude he writes: "For this ought not to be. Medicine as it begins to touch on our higher interests, even the interest of life and death, should feel itself in alliance with higher motives than any which can be thought to help and quicken its pursuit as mere science."

Thomas Sydenham, the "father" of English clinical medicine, and who was born three hundred years ago, gives advice which is worthy of the consideration of every medical man before commencing practice. He points out: (1) The religious duty of the practice of medicine; (2) the religious obligations of medical knowledge; (3) that it is no mean or ignoble animal that he deals with; (4) "that he himself hath no exemption from the common lot . . . ." and is "liable to the same ailments and afflictions with his fellows." He then adds: "For these and like reasons let him strive to render aid to the distressed with greater care, with kindlier spirit, and with stronger fellow feeling." He allows that many in his time were not influenced by these considerations, and adds: "Some are swollen up with pride, and puffed out with the vain conceit of their knowledge: so that these matters seem small in their eyes . . . . The others either gape and grow greedy for gain, or else are borne away by the hopes of some small celebrity; in either case looking to their purses or to their fame." Sydenham was evidently an acute observer of men, as well as disease. He writes of medical practice: ". . . . For I have always thought (and not without reason) that to have published for the benefit of afflicted mortals any certain method of subduing even the slightest disease, was a matter of greater felicity than the riches of a Tantalus or a Crœsus." He also tells us: "I have weighed in a nice and scrupulous balance whether it be better to serve men or to be praised by them, and I prefer the former. And like to a brute beast is the man who has ends and aims other than the advantage of his fellow creatures."

Richard Bright, the distinguished physician to Guy's Hospital, in an introductory lecture to his students in 1832, referred to the responsibilities of the profession for which they were preparing in the following words:—

"To you affectionate children will look for the welfare of their parents; to you the anxious parent will turn for the rescue of his child; and on you the fond husband will depend for all that is dear to him in the hour of danger; to you, perhaps, may be confided the lives of numerous men led to the field of battle, or marched through unwholesome countries; to you the health and efficiency of crews destined to long and perilous navigation may be entrusted; on you the public eye is to be bent in days of plague and pestilence, for who shall now say that from such visitations even our happy climate may be free? And under all these circumstances you must be ready to give an account of what has been done, not only to those who are eagerly collected around you, but to a much more troublesome inquirer within, who will accompany you to the retirement of your closet, and with its inquisitorial voice not only ask you whether you have done your best upon the present occasion, but whether from the time you commenced your professional studies you used your utmost exertions to acquire that knowledge, which would fit you for the discharge of your duties; for it is this consciousness alone which can enable you to lie down with comfort when harassed by the occasional unsuccessful issue even of your best endeavours."

Though the advice of Latham, Sydenham, and Bright just quoted was given so long ago, and to young men who were faced by conditions and opportunities very different from those obtaining to-day, it is striking how applicable are their words to the medical student of 1924, whose elaborate curriculum is charted in this issue of THE LANCET.

VENTILATION OF SUBMARINES.

THE ventilation of submarines with special reference to service in the tropics has been carefully considered by Lieut.-Commander R. F. Jones and Lieut. G. H. Mankin, of the Medical Corps, U.S. Navy, who have reported at length their observations in *U.S. Naval Medical Bulletin* (xx., 6) for June of this year. They supply practical notes on temperature, pressure, and humidity, with remarks on the concurrent conditions of the personnel in submarines cruising on the surface and submerged. They have had large experience, and agree with earlier observers that the increase of carbonic acid (stated as rising to 2·50 per cent. in 13 hours) has little effect during submergences of less than 17 hours; they ascribe the discomforts of life in a submarine submerged rather to the effects of temperature, humidity, and the movement of the air, when they find the kata-thermometer the chief help in investigating the conditions. Their figures are sometimes a little hard to follow, for, apparently, the dry bulb is stated at 87·50° and the temperature of the space at 118° simultaneously, while saturation is claimed, though a difference of a couple of degrees between wet and dry bulbs is recorded. They are of opinion that many of the alleged hardships of submerged cruising were psychical, partly because it was noted that the appetite of the men did not suffer during a ten-hour "dive." The inconveniences are "body odors, fuel-oil smells, and emanations from batteries, from the galley, from lubricating oil." They recommend accordingly better ventilation, with straighter air trunks, more fans in each compartment, a cooling and drying system through which the air of the submerged boat shall be passed, and the separation on deck of the air inlets and outlets, to prevent used, discharged air being again drawn into the boat. Further, they ask for improved w.c. accommodation, greater opportunity for washing, more beds for the men, and ice-boxes for carrying fresh provisions. The average loss of weight in a ten-hour "dive" was about 5 lb., and the barometric pressure rose, within the steel case, about 0·3 in. per hour. Certainly the men in submarines deserve all the comfort that can be given them.

sense, and if a prominent symptom, is mainly aural in origin.

The term *syncope* may with advantage be reserved for a faint with loss of consciousness, and a similar but milder experience without loss of consciousness would be *faintness*. Common experience shows that such symptoms may under given circumstances affect anyone, so that a susceptibility to faint does not imply heart disease. To all of us have been brought children who have fainted, and who have merely on that account been suspected of heart trouble. Children with heart disease are no more liable to faint than children with septic fingers. Syncope has to do with a temporary change in the circulation, probably vagal in origin, but it almost as readily occurs in a healthy circulation as in one which is the seat of disease. There are rare exceptions, such as the syncope of Stokes-Adams syndrome, in which heart disease is the immediate cause of syncope. I am prepared to admit that a faint in later life may have a deeper significance than a faint in adolescence, but even then the cause will oftener prove to be cerebral or cerebro-vascular rather than myocardial, for a faint is not a common failing of a faulty myocardium.

Often *weakness* or exhaustion is ascribed by patients to the heart, though this organ is not responsible. We seldom find patients with heart failure coming to us complaining that they are "weak." I would stress this complaint of weakness as a very characteristic symptom of an exhausted nervous system. When we are tired we do not think of our hearts as being tired, we feel that *we* are tired, referring to ourselves as a nervous organisation. Patients who complain that they must sit down, that a sudden feeling of weakness comes over them, and who thereupon demand a tonic, are not restored by giving digitalis! Of course, this tiredness may not always be a symptom of nervous exhaustion, it may be due to an infection like pulmonary tuberculosis, with its train of toxic effects not only upon the heart as evidenced by a rapid pulse, but upon the neuromuscular system and the ductless glands, the suprarenals in particular.

The cardiac patient has a limited capacity for exertion beyond which he cannot go without distress of a particular kind. Ask the patient what stops him when he is walking, as Sir James Mackenzie advises, and he will give the clue to the cause of his condition. If he stops on account of breathlessness or pain in the chest, the cause is usually cardiovascular. In fact, I would go so far as to say that whenever a patient complains of pain about the sternum when he walks, the diagnosis of a healthy heart is out of the question. In heart disease, early or late, the symptoms are of the same class, the early case differing from the advanced in the matter of degree, not of kind. The exclusive burden in the majority is shortness of breath. Those minor symptoms of which we have spoken are shown for what they are, not truly cardiac, for they have no place even in final failure when, if cardiac, they should be most in evidence. Instead, that unique symptom—breathlessness—is in absolute control as the expression of cardiac distress.

SIGNS.

Now we come to the valuation of the signs of heart disease and at once we are met by the difficulty so often experienced in dealing with patients sent for life assurance or for acceptance into the public services. If an enlarged heart always means a diseased heart, we cannot be too careful before we say that it is enlarged. What, then, are the signs of an enlarged heart that can be misleading? The visible pulsation around the apex-beat may be more diffuse than usual, being more noticeable and even extending as a *ripple* beyond the nipple line. No assumption of enlargement can be based on this appearance, as it is often the natural result of a tachycardia and nothing else. On re-examination after an interval the reduction in pulse-rate will be observed to coincide with the disappearance of the spacious impulse. Another equivocal sign of heart enlargement is the jerky impulse so commonly felt in the ruffled hearts of nervous patients and—pensioners. But an unduly forcible beat, heaving like a billow under the hand, is a reliable sign of heart enlargement; while the combination of displacement and forcefulness makes us more certain than anything else on simple clinical examination that the heart is enlarged. I find the observer *commonly forgets that the only safe definition of* the true apex-beat is the point farthest out and farthest down where there is an impulse which lifts the finger; and through his not palpating with the hand before the finger I have seen him miss an apex-beat which has escaped to the axilla! Occasionally an unusual or double quality in the palpated impulse raises suspicion of mitral stenosis; but an undoubted presystolic thrill—like the purring of a cat, however short—must be stipulated before the *hand* can establish this diagnosis. In speaking of enlargement, I would say that the terms hypertrophy and dilatation as applied to the heart have outlived their term of clinical usefulness. These are changes mainly of interest to the pathologist; physicians may well be content to decide whether enlargement is present or not. Certainly dilatation should never be used as synonymous with failure, for the heart enlarged from disease almost always remains enlarged, and when such a heart does fail it may show little or no further increase in size.

We can no longer rely on percussion as a means of deciding the slight or moderate changes in size which would enter into the question of a healthy heart. Before hazarding the diagnosis of an enlarged heart, without a known cause for it and in the absence of symptoms, it is only prudent to make sure, by the modern development of inspection—radioscopy, or by still more accurate X ray methods now at our disposal, whether the enlargement is real or apparent.

The recognition of a healthy heart leads us next to consider the question of altered *heart sounds*. Heart sounds are weak, or, safer said, distant in so many other conditions that this sign by itself need not raise suspicion of myocardial disease. A loud first sound, especially when it is sudden, may rumour the presence of mitral stenosis, but it would be well to wait for the certainty of a presystolic murmur, as loudness of sound, like an extravagant impulse, may be another misleading effect of increased rate. A duplicated first sound is a common cause of difficulty, for it is constantly present in some healthy persons, and is a frequent accompaniment of high blood pressure. It may be extremely hard to distinguish from a short presystolic murmur.

We are all familiar with the *systolic murmurs* which are a source of trouble, and I do not want to convey any idea that their exploration is easy, for it is not. In brief, when a systolic murmur is heard, does it mean heart disease? That is a common but very important and often perplexing question which faces every physician. What I have said of the history and symptoms bears effectively on the question and provides an answer. Is there merely a systolic murmur and absolutely nothing else to suggest a cardiac lesion? If so, we should not lay too much stress upon it. A systolic murmur, whether at apex or base, if it is softly blowing and unassociated with any enlargement of the heart or with any symptom of heart disease, can in the majority of non-rheumatic cases be ignored. By way of contrast with such a sample of negation, picture the rheumatic child, pallid and breathless, with a long blowing murmur at the apex, loud enough to produce a systolic thrill over an impulse which is displaced and forcible. No one, of course, will assume that a *systolic murmur* appearing during an acute infection, like scarlet fever, or even rheumatic fever, is necessarily of organic origin and a certain precursor of permanent defect: time alone may tell.

I turn next to changes in the rate of the heart—*bradycardia and tachycardia*. We find a patient with

This matter is not so simple, however, when *age changes* in the medical sense may be assumed to have begun. In these degenerative and allied changes which milestone the march of senility, we encounter the third great cause of heart disease, and one which defies exact analysis. Among its results we have, first, disease of the arteries, with its general and localised effects, as in coronary disease; secondly, that disease of unknown origin, and not necessarily senile, in which hypertension is a prominent feature, and which is commonly a dual affection of the cardio-vascular and renal systems.

I submit that there are certain alleged causes of heart disease which need not influence our judgment in deciding as to its presence or absence. In the first place, *nervous strain* is often advanced by patients or their friends as the cause of their symptoms, supposedly cardiac. We are rather tired of the "strained heart," the "disorderly heart" of the pensioner whose nerves are in disorder, the "weak heart" of the neurasthenic; and it would be well for us to forget such hackneyed designations. *Physical strain* has too long been held as a cause of heart disease. When the heart is the seat of an infection we all would agree that exertion will injure it. With this exception, the danger of physical strain per se is now largely discounted. The heart has scarcely ever been proved to have been injured by physical strain alone, and the older reported cases will not bear modern criticism. The "athlete's heart," like the "strained heart," is a myth. It is a striking fact that among the causes even of "soldier's heart" physical exertion alone never took a place of any importance; although, of course, unwonted exertion has often revealed the presence of previously unsuspected cardiac disease.

Next we come to *toxic influences.* In searching for the cause of disease we sometimes find a definite septic focus—as, for example, in the tonsils; when we do not, we imagine a factory of toxins elsewhere, if we are so disposed. Driven by this natural desire to find the cause of an obscure case of disease, we have been induced to focus our attention on teeth, tonsils, intestinal toxæmias. But let me beg of you not to be led away by such conceptions into supposing that we have here a likely cause of chronic heart disease. When toxins which have a selective action on the heart are isolated (and abnormal thyroid products probably include such), it may be different. Toxic substances disarranging metabolism, or disturbing the balance of endocrine activities, may be a cause of general ill-health and physical imbalance without specifically affecting the heart, which only participates in the general debility or functional upheaval. Here let me say that the evidence of tobacco causing permanent disease of the heart is meagre. It is easy to show that in the early reported cases there were associated effects of syphilis or atheroma. Well-authenticated cases due to tobacco alone are very few or non-existent. Smoking has a slight though definite effect in accelerating the heart-rate and raising the blood pressure, these effects being demonstrable during the actual smoking and for some time afterwards. When palpitation is induced by smoking I would ascribe it chiefly to a heightening of the patient's sensibility to extra-systoles or to this increase in the pulse-rate, not to mention its company with indigestion. By far the most important clinical disadvantage of smoking is its tendency to induce pain in the left thoracic region, from which there may be an extension of pain or hyperæsthesia even to the left arm. This is too often unjustifiably diagnosed as "tobacco angina": but if the patient is wise he will have curtailed his smoking before his doctor has been tempted to diagnose such a terrible disease as "angina."

Speaking generally then, in youth or middle age rheumatism and syphilis are the prime causes of chronic heart disease, and in later life high blood pressure or changes in the aorta and other arteries, notably the coronary. Excluding congenital defects, ruling out acute rheumatism and chorea, and with the Wassermann reaction negative, one may say that, unless age or extracardiac disease is beginning to affect the situation, there is most reliable negative evidence to favour the diagnosis of a healthy heart.

SYMPTOMS.

I come now to the symptoms which are more or less provoked by heart disease. I am trying under these various headings to indicate the points which will enable you to diagnose the healthy heart. The first symptom of an unfavourable kind is *shortness of breath.* This is admittedly the capital and almost invariable symptom of heart disease. It is scarcely too much to say that heart disease of importance does not occur unless the breath is short on exertion. Even in angina pectoris, where pain is the characteristic feature, the breath is almost always shortened though only between attacks, not with them. We naturally exclude the non-cardiac causes of dyspnœa with which we are not now concerned. We must, however, be reasonable as regards the breathlessness we find in patients, paying regard to their age, general condition and habits, the character of their work, the opportunities they take for exertion; and we should not neglect to ascertain the lapse of efficiency and duration of the disability by asking the patient to compare his present breathlessness on a customary exertion with what it was, say, a month ago.

In the next place we have thoracic *pain.* There are some who, when they meet a patient complaining of pain in the left side of the chest not within the category of pleurisy, tend to call it angina pectoris, or, if not that, a pain arising from the heart. Now the majority of those with pain in the left side of the chest are not the subjects of heart disease. Angina pectoris is relatively uncommon, while other chest pains are common enough. You will know that aching pain below the left breast is a familiar complaint of neurasthenics and of women at the menopause. It may extend to the left scapula or above the left breast, and even as an ache or heaviness down the left arm. It is almost constant, has no direct relation to exertion, and though it may be rather sharper then, it troubles the patient when at rest and especially when tired. Again, if we find a persistent area of hyperalgesia about the left breast, so that there is tenderness on palpation, we may not take it as an indication of heart trouble. It accompanies the neuralgic pain which has been described, and which may be compared with a headache. Incidentally, let me remark that if we hear of a headache we do not presume disease of the brain; therefore if we hear of a chestache, do not let us presume disease of the heart.

When a patient complains that he feels the beating of his heart, we say that he has *palpitation.* It may be that he feels the irregularity due to extra-systoles when he goes to bed, or is distressed by the heart beating too rapidly or too forcibly on exertion or excitement. Whatever form it takes, palpitation is much oftener significant of nervous hypersensitiveness, worry or indigestion, tea or tobacco, than of cardiac disease. It may be a trivial and transient complaint, a sensory phenomenon without any disturbance of the heart's rate or rhythm, and without any sign of disease. That special form of palpitation described by subjects of paroxysmal tachycardia will later be mentioned. It is a remarkable fact that patients with a failing heart and that most irregular of all arrhythmias, auricular fibrillation, do not complain of palpitation. They have something more distressing—they cannot get their breath!

Giddiness is another symptom which is too readily considered an associate of heart disease and expressive of it. We know it may occur with extreme tachycardia, in arterio-sclerosis, and in high blood pressure, but it is quite a rare symptom in cardiac disease proper. Dizziness or vertigo in a strict history of rheumatism to prevent the fallacious diagnosis of a functional systolic murmur.

Aortic incompetence is the other valvular disease liable to be overlooked unless special care is taken, as it may begin with a quiet, low-pitched short murmur in a patient with few or no symptoms. The only safe plan of detection is to listen at the aortic area and to the left of the sternum in a quiet room, the ear being directly applied to the chest while the patient stops breathing for a moment, with the question in our mind to attune our ear: Is there an aortic diastolic murmur or not? The valvular lesion found among serving soldiers was less often mitral stenosis than aortic incompetence. A patient with mitral stenosis would be too breathless to keep on the march, but a patient with aortic incompetence might not only be able to march but to take part in vigorous sports such as boxing. The lesson for us is that with a definite aortic diastolic murmur, timed by the thumb on the carotid artery, it does not matter much about the history nor much about the symptoms, it is a case of aortic incompetence and not a case of healthy heart.

The third group of cases in which mistakes are apt to arise consists of those with hypertension or *high blood pressure.* We should be particularly alert when we encounter a class of symptom commonly considered peculiar to the menopause, to a neurosis, to obesity. High blood pressure is always a condition to bear in mind when the condition of the heart may be obscured by such concomitants. The woman suffering the manifold symptoms of the menopause may seem to be sufficiently free from indications of cardio-vascular disease until the day her blood pressure is taken. Similarly the sensations of the neurotic may be coloured by the circulatory embarrassment of high blood pressure. When people are very stout we naturally expect them to suffer from breathlessness on exertion, and we are not surprised to find them following the cardiac fashion of stopping at frequent intervals to admire the scenery! Because of this we need not assign to a fat patient the mischievous diagnosis of "fatty heart"; nor, on the other hand, assume that the circulation is healthy because obesity may seem to account for the symptoms. The point I wish to make is that hypertension may be present in obesity and explain symptoms which may wrongly be imputed to other causes. The sphygmomanometer is therefore one of the best instruments to prevent the mistaken diagnosis of a healthy heart, or rather of a healthy circulation; for it permits the proper recognition of cardiac symptoms amid the welter of misleading circumstance, and places us in touch with that very common disease hyperpiesis, or primary high blood pressure, which is responsible for so much suffering and mortality in late middle life and early old age.

In looking at the last of the common difficulties which compass the diagnosis of a healthy heart, allow me to explain why so often the *nervous system* must be taken into account to settle the question, Is our case one of a nervous or a true cardiac disease? There is some justification for patients ascribing their symptoms to the heart when they feel palpitation, especially when the conscious thumping is rapid or irregular. The thought of some heart trouble is naturally prompted when they feel pain below the left breast or feel very weak and tired. These are symptoms which suggest to the patient heart disease, and perhaps to the doctor the same preliminary belief which should as quickly as possible, if found untenable, be dismissed. Apparently functional nervous disease is something of which a patient is ashamed, and so there are substituted cardiac troubles or heart attacks, which are regarded as more honourable. But it has a bad moral effect upon us to allow the false diagnosis of cardiac disease to stand when really the patient is suffering from a neurosis, or from some condition which is the outcome of his neurotic temperament. The false diagnosis draws the attention away from the proper line of treatment, which is one not related to the heart at all, besides being unfair to the relatives, who may be imposed upon by the sufferer and led to imagine that a life is in jeopardy. When faced by the neurasthenic, though his case appears quite plausible as one of cardiac disease, we must not forget all we have learned and seen about such disease, and we must not allow him to retain improperly a diagnosis which, after all, is not even relatively one to be desired.

In conclusion, it will be seen that these difficulties need not dismay us. It is sufficient to remember angina pectoris, early valvular disease, high blood pressure, and functional nervous disease. Having considered and excluded these, we may argue that there has been no adequate cause to affect the heart in question, and it is not enlarged; no more breathlessness occurs on exertion than is natural, and no pain; it works well. We emerge from the inquiry with the diagnosis of a healthy heart, as valuable and beneficent a diagnosis as a doctor could hope to reach. The diagnosis gives the line to treatment. If the heart is healthy it requires no treatment directed to itself, but if we recognise that some other condition is operating, then we shall be well on our way towards treating it.

THE ALKALI RESERVE OF THE BLOOD IN COLIFORM INFECTIONS OF THE KIDNEY.

EFFECT IN SUCH CASES OF TREATMENT WITH ALKALIS.

By ELIZABETH H. LEPPER, O.B.E., M.B., B.S. LOND.,
PATHOLOGIST, ELIZABETH GARRETT ANDERSON HOSPITAL;
AND
E. MARJORIE MARTLAND, M.B., B.S. LOND.,
BIOCHEMIST TO THE HOSPITAL.

THE very marked amelioration of symptoms which occurs on treatment with alkalis in cases of acute pyelitis due to the colon bacillus suggested an investigation into the cause of this improvement. There is no doubt that in the majority of cases the temperature falls, the pain on micturition and the frequency are diminished, and the patient feels very much better; yet the amount of pus and the number of bacilli in the urine are hardly at all decreased. Under these circumstances the immediate general improvement of the patient might conceivably be due either to the successful treatment of a condition of acidosis, or to lessened irritation due to the diminished acidity of the urine.

Alkali Reserve of the Blood in Urinary Infections.

Experimental work on animals was first carried out to discover whether acidosis occurs in infections of the urinary tract with the colon bacillus. Rabbits of 1500 to 2000 g. weight were selected. Catheter specimens of the urine of these animals were cultured, and the urine also examined microscopically for pus and casts, to prove a normal condition of the urinary tract before experiments were begun. An initial estimation of the alkali reserve of the plasma was also made. 3 to 4 c.cm. of blood being collected under paraffin from an ear vein, and the plasma CO_2 estimated in a Van Slyke micro-pipette.

After these preliminary observations had been made, an emulsion of *B. coli* was injected intravenously. Thenceforth the urine, collected from metabolism cages, was examined daily for increase in albumin and for pus and casts; if these appeared. catheter specimens of urine were obtained and cultures made. Estimations of the alkali in the plasma were made within 24 hours of the injection of organisms, and repeated at intervals of a few days as long as the urine showed the presence of an infection.

Of 12 rabbits treated in this way, two died within 24 hours and three showed no infection. The remainder developed urinary infections in varying a slow rate of pulse and ask whether that is a sign of heart trouble. Not necessarily, I may say. The normal heart, free from block, may beat at quite a low rate, as low as 50 or even 40 a minute, though rarely below 50. The patient may naturally have a slow pulse-rate, may be known to have had this peculiarity for years, or the pulse may be found infrequent during convalescence after an infection or after childbirth. These simple bradycardias are easily recognised by the fact that the rate is quickly increased by test exertion. Tachycardia is a far more difficult question, almost as difficult as the question of systolic murmurs. A patient has persistent simple tachycardia which increases on excitement, with exertion, and is reduced by rest though not completely. It lasts for months; digitalis fails to control it, as we have all found out; and we do not know how to stop it. But does it mean heart disease?—that is the question we have to answer. We will dismiss at once those cases in which it springs from pulmonary tuberculosis or hyperthyroidism, and not infrequently from chronic alcoholism. Setting these apart, we find it often associated with a neurosis, but not invariably. There are quite a number of cases of persistent tachycardia in otherwise healthy people without any trace of nervous instability. These are among the mysteries of ordinary clinical practice. Their tachycardia is the only positive sign. I am inclined to think they tend gradually to get better, but exact observation of them on any large scale seems to be wanting. A medical inquirer in general practice may one day give us this information. It is noteworthy that simple tachycardia, unless there is an underlying cause directly affecting the myocardium, does not seem to lead to heart enlargement or indeed failure. In pulmonary tuberculosis the heart is rapid, yet it does not enlarge despite the powerful toxins in circulation.

In modern practice we endeavour to distinguish a paroxysmal tachycardia from all other kinds. If it is an attack that starts abruptly, persists at a fixed high rate for a circumscribed period, and then ends abruptly, we are dealing with a case of paroxysmal tachycardia. If the patient is subject to such attacks, and continues perfectly well and free from abnormal signs in the intervals between them, it may almost be allowed that he has a healthy heart. If an electrocardiogram, taken during an attack, records ordinary paroxysmal tachycardia (and not auricular flutter or fibrillation), such a case is the best example we can quote of a functional heart disease, a term which has so often included little but functional nervous disease.

Then we have heard much in recent years of irregularities of the heart which do not imply heart disease. In children, and in adults too, there is often noticed a respiratory irregularity, sinus arrhythmia, the heart slowing during expiration and quickening during inspiration; and none of us now would take such a thing as a sign of disease. Similarly, if we found extrasystoles in a patient, disappearing on exertion as they do, or a patient complained of what were obvious extrasystoles, we should not take the same line as once was taken. These are not in themselves an index of heart disease, although they may occur along with it.

Before leaving the subject of signs, we have to note the absence of signs of cardiac failure. When we examine a patient with heart disease we are not surprised to find a slight enlargement of the liver, or a few crepitations at the bases of passively congested lungs, or some malleolar œdema. These are what we should look for as signs of failure, and we should not expect to find them in a patient without heart disease. When they are absent in a patient who maintains that he has had heart disease for 12, 15, or 20 years, we begin to ask ourselves whether this really is heart disease, and if it is, why this patient has been so favoured as never to get the signs of cardiac failure.

Therefore, if we get no history of an illness which can produce heart disease, no age changes, no symptoms, and none of the characteristic signs of the kind ordinarily found on examination, we get rather happy in approaching our diagnosis of a healthy heart.

SOURCES OF DIFFICULTY.

It would not be fitting that I should speak of the diagnosis of a healthy heart without referring to the greatest sources of difficulty in its diagnosis because of the mask of physical health which diseased hearts may wear. There are four or five conditions which display such a faint imprint of their cardiac origin that we may easily be misled into believing the heart is healthy when, in fact, it is stricken.

First of all we have *angina pectoris*. I cannot accept any definition of angina pectoris which does not connote danger to life. We all know how varied are the views as to its causation—let us meet on this common ground of understanding. The patient has something which demands diagnosis and treatment and a very careful and judicious prognosis. But the difficulty is that the patient may have angina pectoris and yet not have the signs of heart disease. The size of the heart may be normal, there may be no murmurs, the blood pressure may not be raised, yet the patient has angina pectoris and is confronted with death in each attack. To pursue the question of how we are to tell whether the patient has a healthy heart and has not angina pectoris would take us too far upon a side-line of argument; but in a word or two I would say that we can and must be prepared to diagnose angina pectoris from the patient's statements. Whatever the signs, whatever the history, if a patient complains of a severe pain—or merely an unpleasant pain—in the sternum or even in the breast or arm on exertion, and on exertion only, we dare not say that such a patient has a healthy heart. It is not healthy because it cannot do its work—at any rate, a sustained and reasonable amount of work. Whatever the signs and associations, we should view such cases with great seriousness, and insist on a complete examination to include the electrocardiogram and a Wassermann reaction. For angina pectoris in middle age is mainly due to syphilis and to nothing else. In older people the pathological basis is oftener non-syphilitic aortic and coronary disease. The importance of recognising syphilitic angina is that we have not merely a means of confirming its diagnosis, but a means of treatment which is going to relieve, if not actually cure, many a sufferer otherwise doomed to endure its torment. Mercury and iodide have not lost their power in syphilitic lesions because of the advent of a newer and stronger remedy which here may not always be applied with safety.

A second difficulty may be to decide whether *valvular disease* is present or absent. The absence of a presystolic murmur should not predicate the absence of mitral stenosis. It is most disturbing to find that a patient in whom we have heard this murmur one week has dropped it the next and seems to have a healthy heart. So a loud or sudden first sound, or a double first sound, especially with accentuation of the pulmonary second sound, though not diagnostic of mitral stenosis, may serve to check a too precipitate assertion of its absence. When such sounds are found we must pursue the diagnosis, searching for the murmur by listening at the apex with the patient standing, then immediately after exercise, lying on his left side. A definite presystolic murmur is the positive stamp of stenosis. The commonest effect of mitral rheumatism is the systolic murmur at the mitral area; but, so often does mitral stenosis accompany valvular incompetence, we might say with Graham Steell that a mitral systolic is the commonest murmur of mitral stenosis; stenosis which is necessarily of slower development, and may not produce until later its distinctive murmur. This deeper significance of a mitral systolic lends to it some importance, and justifies my emphasising among other values the history of rheumatism to prevent the fallacious diagnosis of a functional systolic murmur.

Aortic incompetence is the other valvular disease liable to be overlooked unless special care is taken, as it may begin with a quiet, low-pitched short murmur in a patient with few or no symptoms. The only safe plan of detection is to listen at the aortic area and to the left of the sternum in a quiet room, the ear being directly applied to the chest while the patient stops breathing for a moment, with the question in our mind to attune our ear: Is there an aortic diastolic murmur or not? The valvular lesion found among serving soldiers was less often mitral stenosis than aortic incompetence. A patient with mitral stenosis would be too breathless to keep on the march, but a patient with aortic incompetence might not only be able to march but to take part in vigorous sports such as boxing. The lesson for us is that with a definite aortic diastolic murmur, timed by the thumb on the carotid artery, it does not matter much about the history nor much about the symptoms, it is a case of aortic incompetence and not a case of healthy heart.

The third group of cases in which mistakes are apt to arise consists of those with hypertension or *high blood pressure*. We should be particularly alert when we encounter a class of symptom commonly considered peculiar to the menopause, to a neurosis, to obesity. High blood pressure is always a condition to bear in mind when the condition of the heart may be obscured by such concomitants. The woman suffering the manifold symptoms of the menopause may seem to be sufficiently free from indications of cardio-vascular disease until the day her blood pressure is taken. Similarly the sensations of the neurotic may be coloured by the circulatory embarrassment of high blood pressure. When people are very stout we naturally expect them to suffer from breathlessness on exertion, and we are not surprised to find them following the cardiac fashion of stopping at frequent intervals to admire the scenery! Because of this we need not assign to a fat patient the mischievous diagnosis of "fatty heart"; nor, on the other hand, assume that the circulation is healthy because obesity may seem to account for the symptoms. The point I wish to make is that hypertension may be present in obesity and explain symptoms which may wrongly be imputed to other causes. The sphygmomanometer is therefore one of the best instruments to prevent the mistaken diagnosis of a healthy heart, or rather of a healthy circulation; for it permits the proper recognition of cardiac symptoms amid the welter of misleading circumstance, and places us in touch with that very common disease hyperpiesis, or primary high blood pressure, which is responsible for so much suffering and mortality in late middle life and early old age.

In looking at the last of the common difficulties which compass the diagnosis of a healthy heart, allow me to explain why so often the *nervous system* must be taken into account to settle the question, Is our case one of a nervous or a true cardiac disease? There is some justification for patients ascribing their symptoms to the heart when they feel palpitation, especially when the conscious thumping is rapid or irregular. The thought of some heart trouble is naturally prompted when they feel pain below the left breast or feel very weak and tired. These are symptoms which suggest to the patient heart disease, and perhaps to the doctor the same preliminary belief which should as quickly as possible, if found untenable, be dismissed. Apparently functional nervous disease is something of which a patient is ashamed, and so there are substituted cardiac troubles or heart attacks, which are regarded as more honourable. But it has a bad moral effect upon us to allow the false diagnosis of cardiac disease to stand when really the patient is suffering from a neurosis, or from some condition which is the outcome of his neurotic temperament. The false diagnosis draws the attention away from the proper line of treatment, which is one not related to the heart at all, besides being unfair to the relatives, who may be imposed upon by the sufferer and led to imagine that a life is in jeopardy. When faced by the neurasthenic, though his case appears quite plausible as one of cardiac disease, we must not forget all we have learned and seen about such disease, and we must not allow him to retain improperly a diagnosis which, after all, is not even relatively one to be desired.

In conclusion, it will be seen that these difficulties need not dismay us. It is sufficient to remember angina pectoris, early valvular disease, high blood pressure, and functional nervous disease. Having considered and excluded these, we may argue that there has been no adequate cause to affect the heart in question, and it is not enlarged; no more breathlessness occurs on exertion than is natural, and no pain; it works well. We emerge from the inquiry with the diagnosis of a healthy heart, as valuable and beneficent a diagnosis as a doctor could hope to reach. The diagnosis gives the line to treatment. If the heart is healthy it requires no treatment directed to itself, but if we recognise that some other condition is operating, then we shall be well on our way towards treating it.

THE ALKALI RESERVE OF THE BLOOD IN COLIFORM INFECTIONS OF THE KIDNEY.

EFFECT IN SUCH CASES OF TREATMENT WITH ALKALIS.

BY ELIZABETH H. LEPPER, O.B.E., M.B., B.S. LOND.,
PATHOLOGIST, ELIZABETH GARRETT ANDERSON HOSPITAL;
AND
E. MARJORIE MARTLAND, M.B., B.S. LOND.,
BIOCHEMIST TO THE HOSPITAL.

THE very marked amelioration of symptoms which occurs on treatment with alkalis in cases of acute pyelitis due to the colon bacillus suggested an investigation into the cause of this improvement. There is no doubt that in the majority of cases the temperature falls, the pain on micturition and the frequency are diminished, and the patient feels very much better; yet the amount of pus and the number of bacilli in the urine are hardly at all decreased. Under these circumstances the immediate general improvement of the patient might conceivably be due either to the successful treatment of a condition of acidosis, or to lessened irritation due to the diminished acidity of the urine.

Alkali Reserve of the Blood in Urinary Infections.

Experimental work on animals was first carried out to discover whether acidosis occurs in infections of the urinary tract with the colon bacillus. Rabbits of 1500 to 2000 g. weight were selected. Catheter specimens of the urine of these animals were cultured, and the urine also examined microscopically for pus and casts, to prove a normal condition of the urinary tract before experiments were begun. An initial estimation of the alkali reserve of the plasma was also made, 3 to 4 c.cm. of blood being collected under paraffin from an ear vein, and the plasma CO_2 estimated in a Van Slyke micro-pipette.

After these preliminary observations had been made, an emulsion of *B. coli* was injected intravenously. Thenceforth the urine, collected from metabolism cages, was examined daily for increase in albumin and for pus and casts; if these appeared, catheter specimens of urine were obtained and cultures made. Estimations of the alkali in the plasma were made within 24 hours of the injection of organisms, and repeated at intervals of a few days as long as the urine showed the presence of an infection.

Of 12 rabbits treated in this way, two died within 24 hours and three showed no infection. The remainder developed urinary infections in varying

since the urine was voided, the pH of a specimen which at first appeared to be 7·9 might prove to be 7·7 or 7·6 after this treatment. Even after saturation with alveolar air the pH of the urine as excreted would have been a little lower than that found, as the CO_2 tension in the kidney is higher than in alveolar air. The difference would only be significant in the case of very alkaline urines. Further, Davies, Haldane, and Kennaway have shown that the percentage of CO_2 in the alveolar air is raised during the administration of alkalis; the result obtained was, therefore, more alkaline than would have been the case had the specimen been brought into equilibrium with the patient's own alveolar air.

Results.

In all our cases the relief of symptoms, frequency and pain on micturition, backache and fall of temperature went hand in hand with the rise in pH of the urine. Table IV. shows the rapidity with which some of the cases responded to alkaline treatment: there was no delay such as was found by Palmer and Henderson in cases of chronic nephritis, in which 15 to 110 g. a day of alkali were required to bring the pH of the urine to 7·0. The pH of the most alkaline specimen of the series was 8·7. In no case was a pH obtained approaching 9·2, the point at which inhibition of growth of *B. coli* was found by Shohl and Janney to occur in alkaline media. Furthermore, in no case was there more than an insignificant diminution in the number of bacilli and the amount of pus present.

Clinical Notes.

Mrs. G.: Oct. 6th, rigors, vomiting, abdominal pain, frequency. Oct. 8th, no pain or frequency.

Mrs. C.: July 22nd, pain and frequency subsiding immediately on treatment (first specimen obtained two days after admission).

Conclusions.

1. No evidence that a condition of acidosis occurs in acute coliform infections of the urinary tract has been found either experimentally or clinically.
2. The alteration in the amount of pus and bacilli in the urine following alkaline treatment is not sufficient to account for the improvement which takes place in the patient's symptoms.
3. This improvement appears to be definitely associated with a decrease in the hydrogen-ion concentration of the urine, and it is reasonable to suppose that a urine of high hydrogen-ion concentration irritates the inflamed mucous membrane of the urinary tract.

We are greatly indebted to Dr. C. J. Martin for advice regarding the methods used in this investigation and for his helpful criticism of the results obtained.

The greater part of this work was carried out while one of us (E. H. L.) was holding a Beit Memorial Research Fellowship.

CEREBRO-SPINAL FEVER:

A NEW PATHOGENIC CONCEPTION AND ITS IMPORTANCE FOR THE SPECIFIC TREATMENT OF THE DISEASE.

BY DR. KSAWERY LEWKOWICZ,
PROFESSOR OF CHILDREN'S DISEASES, JAGELLONIAN UNIVERSITY,
KRAKÓW (CRACOW, POLAND).

ACCORDING to C. Worster-Drought and A. Mills Kennedy, "in man, for whom the meningococcus is definitely pathogenic, there is overwhelming evidence that the meninges are pre-eminently the site of election for this organism." The cocci, "on reaching the blood-stream from the naso-pharynx, are quickly carried to their destination," as if directed by some voluntary effort or by a mysterious power—their presumptive affinity for meningeal structures—"leave the blood-stream and localise in the subarachnoid space."

It would be easy to quote almost identical or similar opinions of the most competent authorities from the French (Dopter), German (Gruber and Kerschensteiner), or Polish (Droba and Kuczera) medical literature. Nevertheless, this "overwhelming evidence" is far from being as indisputable as it seems at first sight; and even in the monograph of the above-mentioned English authors we meet with details well adapted to disturb this rather excessive assurance. I mean particularly the cases intermediate in character between the pure septicæmic variety of the meningococcal infection and the ordinary fulminating type with meningitis. "In these cases, the course lasts only from 24 to 48 hours: blood cultures or cultivations from the heart blood taken post mortem yield meningococci. The brain and spinal cord may be practically normal in appearance or the ventricle may contain a small quantity of turbid fluid. The ventricular fluid, however, when planted out on to a suitable medium, gives growth of meningococci."

Route of Invasion of the Meningococcus.

According to these records, made by Herringham and Thornley and Symmers, to which we may add further analogous cases from Droba and Kuczera, Drigalski and Goeppert, it would appear quite evident that the meningococcus penetrates into the ventriculo-subarachnoid system, contrary to the hitherto expressed opinions, not through the meninges but through the choroid plexuses. This latter view is strongly corroborated by the histological investigations of Dopter who, in fulminating cases, found an acute inflammation of the plexuses, and in his monograph illustrates this change by very instructive figures. In cases having a longer course, this lesion seems to retrograde quickly in the subsequent stages of the disease.

The invasion of the meninges—i.e., of the primarily and chiefly affected arachnoid-mater, by the meningococcus directly from the circulation, appears quite incomprehensible, as this membrane is non-vascular. On the contrary, we can easily understand that during the bacteriæmic "pre-meningitic" stage a metastatic focus—analogous to the foci seen in the skin under the shape of various rashes—may develop in either of the choroid plexuses—richly vascular, secretory organs, to be regarded as a sort of cerebral kidney. Owing to the peculiar structure of the plexus-villi, the focus soon reaches and infects their epithelial lining. The infection, at first local, subsequently extends rapidly, finally constituting a general ventriculitis, encephalo-coilitis (ἐγκέφαλος, brain, and κοιλία, cavity), or choroido-ependymitis.

The meningococcus is in truth a very slightly pathogenic organism, but its feeble virulence is largely counterbalanced by its remarkable power of multiplying, which enables it to appear sometimes in the blood films, or at least to provoke extremely extensive maculo-papular, petechial, or purpuric rashes scarcely ever met with in other septicæmic infections. The degrees. Two became acutely ill; one of these died after five days, autopsy showing a slight bilateral pyelitis, marked inflammation of the vesiculæ seminales and also of the gall-bladder, the bacillus injected being recovered from the urine and bile; the other showed small cortical abscesses in both kidneys, and very marked inflammation of the left testis from which the bacillus was recovered. Two other rabbits developed chronic urinary infections, pus and bacilli persisting in the urine for five weeks, and three showed a transient infection of the urine lasting only a few days.

In none of these cases was there evidence of a permanent acidosis. In seven out of eight rabbits examined within 24 hours the plasma bicarbonate showed a diminution varying from 6 to 20 per cent. This is in accordance with the findings of Hirsch, who observed an immediate fall of the plasma alkali following the intravenous injection of various organisms. In every case, however, this initial drop was followed by a return to normal within 48 hours, which was maintained as long as the animal was under observation.

It was, however, recognised that the rabbit is not an ideal animal for this research. Chronic infections are difficult to produce, and acute infections are too rapidly fatal to be useful for experimental purposes. Observations on the blood cannot be made sufficiently often, owing to the severe degree of anæmia produced by repeated bleedings. Furthermore, the rabbit when ill will eat only the cabbage in its food, leaving the oats, and any slight degree of acidosis might thus be masked by the diet.

For these reasons, experiments on animals were abandoned, and a series of observations was undertaken on the alkali reserve of hospital cases of acute *B. coli* pyelitis. The cases were under the care of Mrs. E. E. Flemming, M.D., and Miss D. C. Hare, M.R.C.P., to whom our grateful thanks are due for the facilities given us. Only those cases who were sufficiently ill to require treatment as in-patients were examined. The estimation of the alkali reserve was made, whenever possible, before treatment was begun, as well as at intervals during subsequent treatment with alkaline or acid salts. The plasma bicarbonate was estimated in most cases in capillary blood taken from the ear, using Martin's method, which we find gives the same results as those obtained by using a Van Slyke pipette. The percentage of CO_2 corresponding to these titrations in the capillary blood of 11 presumably normal people averaged 57·5 per cent., the actual figures varying from 47·5 to 68·5 per cent.

The results of observations made on six patients suffering from *B. coli* pyelitis before treatment had been begun are shown in Table I.

It will be seen that in none of these cases was there any diminution of the alkali reserve of the plasma sufficient to be considered abnormal. Tables II. and III. show the very slight effects produced in the alkali reserve of the plasma of the same patient by treatment either with alkalis or acids. The improvement in symptoms in such cases cannot, therefore, be due to the neutralisation of an acidosis, for the condition did not exist.

Influence of Treatment on Reaction of Urine.

Dismissing the question of an acidosis, we then considered the possibility that the acid urine, constantly found in these cases before treatment, irritated the inflamed mucous membrane of the urinary tract, and that the improvement on treatment with alkalis was due to the substitution of this irritating fluid by a neutral or alkaline urine. Preliminary observations were then made to study the effect of solutions of varying pH upon tissues denuded of their epithelium. Mixtures of acid and basic phosphates, isotonic with the blood, varying in pH from 4·0 to 9·0, were made up. Into these was dipped a finger with a newly inflicted cut or abrasion of the skin. It was found that a solution of pH 4 caused acute pain; between 5 and 6 a stinging sensation was produced, and between 6 and 7 a slight but definite discomfort and smarting. Solutions of pH higher than this had no effect till pH 9·0 was reached; this was found to be definitely soothing to an irritated surface. Comparable experiments were also made upon the mucous membrane at the urethral orifice in patients under treatment for urethritis. These, however, proved to be of little value; there was in every case complete insensitiveness to any of our solutions, probably accounted for by much previous treatment with strong disinfectants, some of which. such as 1 per cent. lactic acid, had a pH far lower than that of our phosphate mixtures.

We then made a series of observations on the urines of hospital patients undergoing medical treatment of pyelitis due to *B. coli*, to find out whether the improvement in the symptoms could be correlated with the alteration in the reaction of the urine. Specimens of urine were collected twice daily in wide-necked bottles containing toluene, which were filled to the brim with the freshly passed specimen and stopper replaced. Kept in this way there was only a slight loss of CO_2. The pH of the urine was estimated by the method described below; at the same time a note was made of the amount of pus and bacilli present.

Method of Estimating the pH of Urine.

A rough idea of the pH of the urine was obtained by noting the colour it produced with various indicators on a porcelain matching-plate. 5 c.cm. o the specimen were then measured into a standard test-tube. 0·5 c.cm. of the appropriate indicator added. and the colour matched with standard phosphate mixtures of known pH in a comparator. the colour of the urine being compensated in the usual way. If the pH were greater than 7·0. the urine was saturated with the alveolar air of the observer until no change of colour occurred. If CO_2 had escaped since the urine was voided, the pH of a specimen which at first appeared to be 7·9 might prove to be 7·7 or 7·6 after this treatment. Even after saturation with alveolar air the pH of the urine as excreted would have been a little lower than that found, as the CO_2 tension in the kidney is higher than in alveolar air. The difference would only be significant in the case of very alkaline urines. Further, Davies, Haldane, and Kennaway have shown that the percentage of CO_2 in the alveolar air is raised during the administration of alkalis; the result obtained was, therefore, more alkaline than would have been the case had the specimen been brought into equilibrium with the patient's own alveolar air.

Results.

In all our cases the relief of symptoms, frequency and pain on micturition, backache and fall of temperature went hand in hand with the rise in pH of the urine. Table IV. shows the rapidity with which some of the cases responded to alkaline treatment; there was no delay such as was found by Palmer and Henderson in cases of chronic nephritis, in which 15 to 110 g. a day of alkali were required to bring the pH of the urine to 7·0. The pH of the most alkaline specimen of the series was 8·7. In no case was a pH obtained approaching 9·2, the point at which inhibition of growth of *B. coli* was found by Shohl and Janney to occur in alkaline media. Furthermore, in no case was there more than an insignificant diminution in the number of bacilli and the amount of pus present.

Clinical Notes.

Mrs. G.: Oct. 6th, rigors, vomiting, abdominal pain, frequency. Oct. 8th, no pain or frequency.

Mrs. C.: July 22nd, pain and frequency subsiding immediately on treatment (first specimen obtained two days after admission).

Conclusions.

1. No evidence that a condition of acidosis occurs in acute coliform infections of the urinary tract has been found either experimentally or clinically.
2. The alteration in the amount of pus and bacilli in the urine following alkaline treatment is not sufficient to account for the improvement which takes place in the patient's symptoms.
3. This improvement appears to be definitely associated with a decrease in the hydrogen-ion concentration of the urine, and it is reasonable to suppose that a urine of high hydrogen-ion concentration irritates the inflamed mucous membrane of the urinary tract.

We are greatly indebted to Dr. C. J. Martin for advice regarding the methods used in this investigation and for his helpful criticism of the results obtained.

The greater part of this work was carried out while one of us (E. H. L.) was holding a Beit Memorial Research Fellowship.

CEREBRO-SPINAL FEVER:

A NEW PATHOGENIC CONCEPTION AND ITS IMPORTANCE FOR THE SPECIFIC TREATMENT OF THE DISEASE.

BY DR. KSAWERY LEWKOWICZ,
PROFESSOR OF CHILDREN'S DISEASES, JAGELLONIAN UNIVERSITY, KRAKÓW (CRACOW, POLAND).

ACCORDING to C. Worster-Drought and A. Mills Kennedy, "in man, for whom the meningococcus is definitely pathogenic, there is overwhelming evidence that the meninges are pre-eminently the site of election for this organism." The cocci, "on reaching the blood-stream from the naso-pharynx, are quickly carried to their destination," as if directed by some voluntary effort or by a mysterious power—their presumptive affinity for meningeal structures—"leave the blood-stream and localise in the subarachnoid space."

It would be easy to quote almost identical or similar opinions of the most competent authorities from the French (Dopter), German (Gruber and Kerschensteiner), or Polish (Droba and Kuczera) medical literature. Nevertheless, this "overwhelming evidence" is far from being as indisputable as it seems at first sight; and even in the monograph of the above-mentioned English authors we meet with details well adapted to disturb this rather excessive assurance. I mean particularly the cases intermediate in character between the pure septicæmic variety of the meningococcal infection and the ordinary fulminating type with meningitis. "In these cases, the course lasts only from 24 to 48 hours; blood cultures or cultivations from the heart blood taken post mortem yield meningococci. The brain and spinal cord may be practically normal in appearance or the ventricle may contain a small quantity of turbid fluid. The ventricular fluid, however, when planted out on to a suitable medium, gives growth of meningococci."

Route of Invasion of the Meningococcus.

According to these records, made by Herringham and Thornley and Symmers, to which we may add further analogous cases from Droba and Kuczera, Drigalski and Goeppert, it would appear quite evident that the meningococcus penetrates into the ventriculo-subarachnoid system, contrary to the hitherto expressed opinions, not through the meninges but through the choroid plexuses. This latter view is strongly corroborated by the histological investigations of Dopter who, in fulminating cases, found an acute inflammation of the plexuses, and in his monograph illustrates this change by very instructive figures. In cases having a longer course, this lesion seems to retrograde quickly in the subsequent stages of the disease.

The invasion of the meninges—i.e., of the primarily and chiefly affected arachnoid-mater, by the meningococcus directly from the circulation, appears quite incomprehensible, as this membrane is non-vascular. On the contrary, we can easily understand that during the bacteriæmic "pre-meningitic" stage a metastatic focus—analogous to the foci seen in the skin under the shape of various rashes—may develop in either of the choroid plexuses—richly vascular, secretory organs, to be regarded as a sort of cerebral kidney. Owing to the peculiar structure of the plexus-villi, the focus soon reaches and infects their epithelial lining. The infection, at first local, subsequently extends rapidly, finally constituting a general ventriculitis, encephalo-coilitis (ἐγκέφαλος, brain, and κοιλία, cavity), or choroido-ependymitis.

The meningococcus is in truth a very slightly pathogenic organism, but its feeble virulence is largely counterbalanced by its remarkable power of multiplying, which enables it to appear sometimes in the blood films, or at least to provoke extremely extensive maculo-papular, petechial, or purpuric rashes scarcely ever met with in other septicæmic infections. The

susceptibility, the lack of resistance of the organism, however—not its movement towards the meninges—constitutes the real reason why the general blood infection is, as a rule, of very short duration. In fact, as soon as the patient develops even the slightest degree of general immunity, the meningococci present in the circulation are impaired in vitality, lose their power to bring about metastatic lesions, and finally are completely destroyed. The former foci in the depth of the tissues disappear in a few days; and the rapid retrocession of the cutaneous changes offers us an excellent opportunity of following this process closely. Occasional metastatic lesions in the meninges, if they exist at all, must exhibit, no doubt, the same retrograde evolution, for the specific defence substances of the blood have as completely free access to these thecæ with their endothelial lining as to any other serous membrane or parenchymatous organ. Besides, whenever a certain part of the subarachnoid space—e.g., the spinal theca—is cut off from communication with the ventricles and thus ceases to be continually infected, the meningococci there disappear immediately, and the inflammation thereupon assumes a serous character. This must be regarded as the best proof that an autonomous meningitis independent of the ventricular process does not exist at all.

The conditions encountered by the infectious process in the cerebral ventricles are fundamentally different. The surface of these cavities is ontologically external, and possesses, in contrast with the meninges, not an endothelial but an epithelial lining. This layer constitutes normally for the proteins, and thus also for the antibodies of the blood, an almost impenetrable barrier; and even in the course of ventriculitis, when the inflammatory exudate carries some amount of plasma into the ventricular cavities, this obstacle is very serious. It is also of great import that this exudate is continually diluted by the cerebro-spinal fluid secreted in the ventricles. So we must conclude that the meningococci find in the cerebral ventricles extraordinarily favourable conditions for their existence, even more favourable than those upon the mucous membranes of the respiratory passages. Consequently, they can maintain themselves here for weeks, and even for months sometimes, while the continuance of any other deep infectious focus has long become quite impossible.

To emphasise that, in the above conception of meningococcal infection, we are not compelled to assume any mysterious faculty, for instance any special affinity of the meningococcus; it is sufficient to assume that it has certain properties which can be easily ascertained: (1) the ability to live in and upon the epithelial lining of the respiratory passages or of the cerebral ventricles; (2) surprising power of multiplying, but only (3) a slight power of resistance.

Course of the Disease.

In the course of the disease, three *étapes* may be distinguished: (1) meningococcal grippe, the only localisation apt to spread and to form epidemics, as pointed out by the author in 1905, and by Dopter in 1909; (2) septicæmia; and (3) choroido-ependymitis. The *étapes* do not constitute definite stages (periods), as only the second is transient, while the first and the third may last simultaneously for weeks and months. In the first, the process, affecting comparatively resistant structures, chiefly the naso-pharynx, is generally characterised by quite insignificant reactive symptoms.

When comparing systematically, during the course of cerebro-spinal fever, the fluid afforded by ventricular puncture and that obtained from the spinal theca, we soon find that the meningococci multiply principally, or rather exclusively, in the ventricles; and the spinal fluid contains only those cocci that it brought on passing from the ventricles into the subarachnoid space. In addition to this, both fluids generally differ greatly in their qualities, even in cases where there is no evidence of any serious obstacle to communication between them. Two cardinal types may be distinguished.

In the one, the reactive inflammation of the ventricles is quite insufficient; their fluid may appear quite clear to the naked eye; the white cells therein are very few, the mononuclears, lymphocytes, and epithelial cells are largely predominant or exclusively present; in short, suppuration is practically absent, and the reactive process has the character of serous inflammation or even simple irritation. Nevertheless, the ventricular fluid is sometimes directly crowded with extracellular diplococci, and the films may give the appearance of a pure culture. Now, fluid of such character is being continually evacuated into the subarachnoid space, and it is not till it gets there that definite reactive phenomena, suppuration, phagocytosis, and bacteriolysis take place to a greater or less extent. It is evident that the proper and real site of infection lies here in the ventricles, although the suppurative inflammation is completely confined to the meninges.

The other type arises in its purest form when an energetic suppuration, together with phagocytosis and bacteriolysis, has already developed in the ventricles. Films from the ventricular fluid may then exhibit almost the same picture as those from the spinal fluid. A leucocyte count, it is true, shows figures that are from several times to several scores of times as large for the spinal fluid as those for the ventricular fluid. The conclusion, however, that the leucocytes have originated from the particularly active subarachnoid suppuration, must appear erroneous, as the albumin content of both fluids is practically equal. We are compelled to admit that the white cells with their ingested meningococci have almost all come from the ventricles. Their increase in the subarachnoid space is brought about by the resorption of the fluid parts, while the cellular elements are retained by the thecal membrane acting as a filter. An identical opinion has been already expressed by Tinel as to the sheaths of spinal nerve roots, on account of the fact that, on histological examination, they exhibit no inflammatory vascular or perivascular reaction and no infectious nodules.

Explanation of the Anatomical Lesions.

All this brings us directly to the most interesting problem of the explanation of the anatomical lesions. Indeed, if cerebro-spinal fever has been hitherto regarded as a primary purulent meningitis with ventriculitis as a possible secondary, but not necessary lesion; this opinion is based upon the fact that in earlier stages of the disease the ventricular changes are often very slight and sometimes appear to be absent (to the naked eye), while thick and extensive layers of purulent exudate cover the meninges. So authors were induced to assume that this pus is formed in situ as a result of local purulent inflammation. In this supposition, however, they did not take into consideration that the ventriculo-subarachnoid system is filled with fluid which exhibits a certain current, slight, it is true, but nevertheless permanent, as it is secreted exclusively in the cerebral ventricles by the choroid plexuses, and absorbed exclusively throughout the extent of the subarachnoid space. On account of this current we are brought to consider the possibility that the pus cells found upon the meninges may sometimes, indeed, have been produced in situ, if the membrane received for absorption a fluid charged with free meningococci; but that, more frequently, they draw their origin from the ventricles or other parts of the meninges, and only settle down upon the thecal membrane as upon a filter. The largest accumulations of pus must thus arise in the areas where absorption of the fluid is most active. As of the two leptomeninges the arachnoid mater is the chief absorbent one, it will also be more affected. As regards distribution of the pus over the cerebral surface, it principally accumulates over the frontal and the anterior part of the parietal lobes, as we may suppose, because

that is the highest part of the cranial cavity in a reclining patient; and thus the venules of the subarachnoid space must here show the lowest, perhaps even a negative blood pressure, and can exercise, upon the fluid of the perivascular spaces which are continuous with the subarachnoid cavity, a definite sucking action. For accumulation of pus in the spinal theca, sedimentation may also be of some import.

As to the rest, a whole series of factors exist contributing to shape the anatomical picture and let it appear in very numerous modifications: varying intensity of the ventricular infection, different degrees of the reactive phenomena in the ventricles and subarachnoid space, varying level reached by the general immunisation, various impairment of the choroid plexuses in their secretory function; but, first of all, the varying degree of the inflammatory cerebral œdema, and the different modes of behaviour of the cerebral tissue in face of the condition of pressure resulting from œdematous swelling of the brain and the fact that this organ is shut up in a cavity having quite rigid walls.

Effects of Cerebral Œdema.

The highest degrees of cerebral œdema lead by means of circulatory disturbance to death in a fulminating manner; we may here speak of incarceration of the brain. In the acute fatal type, when puncturing the ventricles during life, we obtain an abundant flow of venous blood from different depths as a sign of passive congestion, and in autopsy the picture of cerebral purpura is sometimes well developed. The lumen of the ventricles is considerably narrowed.

If the consistence of the brain is uncommonly soft and flaccid, a condition frequently met with in infants, especially in those bottle-fed, the cerebral œdema and condition of pressure result soon in the narrowing, closing, and finally the obliterating of the sulci of the cerebral convexity. Now, in those parts of the subarachnoid space that have thus lost their connexion with the ventricles, both the infectious and the inflammatory processes disappear immediately. As larger masses of dense pus have not yet had an opportunity to develop, and as fluid containing only moderate amounts of pus cells vanishes readily by absorption, without leaving a trace, the leptomeninges of the convexity may afterwards appear quite unchanged, or, very rarely, some fragile adhesion with the dura mater remains as the only vestige of the completed process. In other cases, however, if larger purulent layers are already present in the sulci, the pus undergoes no absorption, but disintegrates, and is then penetrated by young connective tissue, finally forming in the meninges sclerotic and thickened plaques. After the sulci of the convexity and the anterior part of the base have been closed, the cisternæ of the base remain the only part of the subarachnoid space, within the cranial cavity, that communicates with the ventricles. Consequently, these alone will be filled up with pus. We thus get a full explanation of the pathogeny, hitherto obscure, of the posterior basic type as found in infants.

Swelling of the brain may further bring about a wedging of the oblong cord and the adjacent parts of the cerebellum into the foramen occipitale magnum. In autopsy, the wedged-in parts are separated from the rest by a marked furrow, being the impression of the edge of the foramen. The condition is associated with narrowing of the subarachnoid spaces within the wedged-in parts, and, in life, with signs of impairment of communication between the cerebral and spinal fluids. It may finally result in complete obliteration of the narrowed spaces, eventually fixed by adhesions.

According to my investigations, and contrary to the opinions expressed by many authors, the production of the fluid in the ventricles is never increased, but is lessened throughout the course of cerebro-spinal fever; the pressure of the fluid is therefore only moderately increased, normal, or even lowered. Nor have I ever found obstruction of the foramina Luschki or foramen Magendii. The above-mentioned changes, however, both constituting a consequence of cerebral œdema—i.e., obliteration of the sulci of the cerebral convexity and impairment of communication with the spinal canal, together with inflammatory changes of the membranes confining the basal cisternæ are quite sufficient to explain the pathogeny of hydrocephalus, as they all contribute greatly to impede the drainage of the ventricles.

With the progress of age, the consistence of the brain becomes more and more firm and resistant. Consequently, changes of configuration that would lead to obliteration of the cerebral sulci can develop only after a long duration. The subarachnoid spaces of the convexity thus remaining perfectly passable for a long time, are therefore the site of an active resorption of the fluid, and also of an abundant accumulation of its cellular elements. As the drainage of the ventricles is sufficient, at least in the earlier stages, hydrocephalus does not develop. On the other hand, the brain having but little possibility to change its configuration and to withdraw in that way from the pressure exercised on it by the osseous cranial walls—the pressure of the fluid is quite a different matter—suffers more through this condition, which in its turn manifests itself by violent cerebral symptoms.

In infants with their plastic brain, the cerebral manifestations are, on the contrary, quite colourless, and so the disease remains very often undiagnosed, not only by general practitioners, but sometimes even by most competent examiners. So, when J. Thomson, speaking about the posterior basic meningitis in infants, states that "in a considerable proportion of cases . . . there is a history of antecedent catarrh of the nose, bronchi, or intestines"; that "the three cardinal symptoms of the early stage are *head retraction*, *vomiting*, and *convulsions*," I must admit that I think there is some error in these statements, because I never saw a meningitis begin in that way, and had plenty of opportunities to meet with cases remaining undiagnosed until the third week. Thus, so far as my experience goes, the presumptive antecedent catarrh is to be regarded as the initial period of definite meningitis, and the symptoms of the supposed early stage as a condition of definitely constituted hydrocephalus. To become persuaded of the truth of this assertion, it is sufficient to determine the width of the ventricles: they are already, in the latter stage, considerably dilated, the lumen measuring about 30 mm.

The Ventricles the Essential Site of Infection.

The notion that, in cerebro-spinal fever, the ventricles constitute the only really essential site of infection is, no doubt, of great import for serotherapy, for it points out the fact that this cardinal focus must be attacked first of all by serum, the presence of serum in the subarachnoid space being without significance. In fact, we may count upon a therapeutic effect only if the concentration of serum throughout the ventricular system is so high that it lets the fluid give, with the emulsion of the autogenous strain of meningococcus, the complement-fixation reaction. This concentration must be maintained during several days until the examination of the ventricular fluids—the state of the spinal fluid is unreliable—shows absence of meningococci.

In most cases this aim is easily attained even by epimedullar administration—i.e., by injecting the serum through the lumbar puncture. Indeed, when letting out, before injection, a sufficiently large amount of fluid, injecting adequately large doses of serum, and repeating the procedure every day, we can find—using for the determination a specific anti-horse precipitating serum—the concentration of serum in the ventricular fluid, shortly after epimedullar injection, as high as about 10 per cent., and after 24 hours, before the next injection, not lower than 3, or, at least, 1 per cent. If the standard of

susceptibility, the lack of resistance of the organism, however—not its movement towards the meninges—constitutes the real reason why the general blood infection is, as a rule, of very short duration. In fact, as soon as the patient develops even the slightest degree of general immunity, the meningococci present in the circulation are impaired in vitality, lose their power to bring about metastatic lesions, and finally are completely destroyed. The former foci in the depth of the tissues disappear in a few days; and the rapid retrocession of the cutaneous changes offers us an excellent opportunity of following this process closely. Occasional metastatic lesions in the meninges, if they exist at all, must exhibit, no doubt, the same retrograde evolution, for the specific defence substances of the blood have as completely free access to these thecæ with their endothelial lining as to any other serous membrane or parenchymatous organ. Besides, whenever a certain part of the subarachnoid space—e.g., the spinal theca—is cut off from communication with the ventricles and thus ceases to be continually infected, the meningococci there disappear immediately, and the inflammation thereupon assumes a serous character. This must be regarded as the best proof that an autonomous meningitis independent of the ventricular process does not exist at all.

The conditions encountered by the infectious process in the cerebral ventricles are fundamentally different. The surface of these cavities is ontologically external, and possesses, in contrast with the meninges, not an endothelial but an epithelial lining. This layer constitutes normally for the proteins, and thus also for the antibodies of the blood, an almost impenetrable barrier; and even in the course of ventriculitis, when the inflammatory exudate carries some amount of plasma into the ventricular cavities, this obstacle is very serious. It is also of great import that this exudate is continually diluted by the cerebro-spinal fluid secreted in the ventricles. So we must conclude that the meningococci find in the cerebral ventricles extraordinarily favourable conditions for their existence, even more favourable than those upon the mucous membranes of the respiratory passages. Consequently, they can maintain themselves here for weeks, and even for months sometimes, while the continuance of any other deep infectious focus has long become quite impossible.

To emphasise that, in the above conception of meningococcal infection, we are not compelled to assume any mysterious faculty, for instance any special affinity of the meningococcus; it is sufficient to assume that it has certain properties which can be easily ascertained: (1) the ability to live in and upon the epithelial lining of the respiratory passages or of the cerebral ventricles; (2) surprising power of multiplying, but only (3) a slight power of resistance.

Course of the Disease.

In the course of the disease, three *étapes* may be distinguished: (1) meningococcal grippe, the only localisation apt to spread and to form epidemics, as pointed out by the author in 1905, and by Dopter in 1909; (2) septicæmia; and (3) choroido-ependymitis. The *étapes* do not constitute definite stages (periods), as only the second is transient, while the first and the third may last simultaneously for weeks and months. In the first, the process, affecting comparatively resistant structures, chiefly the naso-pharynx, is generally characterised by quite insignificant reactive symptoms.

When comparing systematically, during the course of cerebro-spinal fever, the fluid afforded by ventricular puncture and that obtained from the spinal theca, we soon find that the meningococci multiply principally, or rather exclusively, in the ventricles; and the spinal fluid contains only those cocci that it brought on passing from the ventricles into the subarachnoid space. In addition to this, both fluids generally differ greatly in their qualities, even in cases where there is no evidence of any serious obstacle to communication between them. Two cardinal types may be distinguished.

In the one, the reactive inflammation of the ventricles is quite insufficient; their fluid may appear quite clear to the naked eye; the white cells therein are very few, the mononuclears, lymphocytes, and epithelial cells are largely predominant or exclusively present; in short, suppuration is practically absent, and the reactive process has the character of serous inflammation or even simple irritation. Nevertheless, the ventricular fluid is sometimes directly crowded with extracellular diplococci, and the films may give the appearance of a pure culture. Now, fluid of such character is being continually evacuated into the subarachnoid space, and it is not till it gets there that definite reactive phenomena, suppuration, phagocytosis, and bacteriolysis take place to a greater or less extent. It is evident that the proper and real site of infection lies here in the ventricles, although the suppurative inflammation is completely confined to the meninges.

The other type arises in its purest form when an energetic suppuration, together with phagocytosis and bacteriolysis, has already developed in the ventricles. Films from the ventricular fluid may then exhibit almost the same picture as those from the spinal fluid. A leucocyte count, it is true, shows figures that are from several times to several scores of times as large for the spinal fluid as those for the ventricular fluid. The conclusion, however, that the leucocytes have originated from the particularly active subarachnoid suppuration, must appear erroneous, as the albumin content of both fluids is practically equal. We are compelled to admit that the white cells with their ingested meningococci have almost all come from the ventricles. Their increase in the subarachnoid space is brought about by the resorption of the fluid parts, while the cellular elements are retained by the thecal membrane acting as a filter. An identical opinion has been already expressed by Tinel as to the sheaths of spinal nerve roots, on account of the fact that, on histological examination, they exhibit no inflammatory vascular or perivascular reaction and no infectious nodules.

Explanation of the Anatomical Lesions.

All this brings us directly to the most interesting problem of the explanation of the anatomical lesions. Indeed, if cerebro-spinal fever has been hitherto regarded as a primary purulent meningitis with ventriculitis as a possible secondary, but not necessary lesion; this opinion is based upon the fact that in earlier stages of the disease the ventricular changes are often very slight and sometimes appear to be absent (to the naked eye), while thick and extensive layers of purulent exudate cover the meninges. So authors were induced to assume that this pus is formed in situ as a result of local purulent inflammation. In this supposition, however, they did not take into consideration that the ventriculo-subarachnoid system is filled with fluid which exhibits a certain current, slight, it is true, but nevertheless permanent, as it is secreted exclusively in the cerebral ventricles by the choroid plexuses, and absorbed exclusively throughout the extent of the subarachnoid space. On account of this current we are brought to consider the possibility that the pus cells found upon the meninges may sometimes, indeed, have been produced in situ, if the membrane received for absorption a fluid charged with free meningococci; but that, more frequently, they draw their origin from the ventricles or other parts of the meninges, and only settle down upon the thecal membrane as upon a filter. The largest accumulations of pus must thus arise in the areas where absorption of the fluid is most active. As of the two leptomeninges the arachnoid mater is the chief absorbent one, it will also be more affected. As regards distribution of the pus over the cerebral surface, it principally accumulates over the frontal and the anterior part of the parietal lobes, as we may suppose, because

that is the highest part of the cranial cavity in a reclining patient; and thus the venules of the subarachnoid space must here show the lowest, perhaps even a negative blood pressure, and can exercise, upon the fluid of the perivascular spaces which are continuous with the subarachnoid cavity, a definite sucking action. For accumulation of pus in the spinal theca, sedimentation may also be of some import.

As to the rest, a whole series of factors exist contributing to shape the anatomical picture and let it appear in very numerous modifications: varying intensity of the ventricular infection, different degrees of the reactive phenomena in the ventricles and subarachnoid space, varying level reached by the general immunisation, various impairment of the choroid plexuses in their secretory function; but, first of all, the varying degree of the inflammatory cerebral œdema, and the different modes of behaviour of the cerebral tissue in face of the condition of pressure resulting from œdematous swelling of the brain and the fact that this organ is shut up in a cavity having quite rigid walls.

Effects of Cerebral Œdema.

The highest degrees of cerebral œdema lead by means of circulatory disturbance to death in a fulminating manner; we may here speak of incarceration of the brain. In the acute fatal type, when puncturing the ventricles during life, we obtain an abundant flow of venous blood from different depths as a sign of passive congestion, and in autopsy the picture of cerebral purpura is sometimes well developed. The lumen of the ventricles is considerably narrowed.

If the consistence of the brain is uncommonly soft and flaccid, a condition frequently met with in infants, especially in those bottle-fed, the cerebral œdema and condition of pressure result soon in the narrowing, closing, and finally the obliterating of the sulci of the cerebral convexity. Now, in those parts of the subarachnoid space that have thus lost their connexion with the ventricles, both the infectious and the inflammatory processes disappear immediately. As larger masses of dense pus have not yet had an opportunity to develop, and as fluid containing only moderate amounts of pus cells vanishes readily by absorption, without leaving a trace, the leptomeninges of the convexity may afterwards appear quite unchanged, or, very rarely, some fragile adhesion with the dura mater remains as the only vestige of the completed process. In other cases, however, if larger purulent layers are already present in the sulci, the pus undergoes no absorption, but disintegrates, and is then penetrated by young connective tissue, finally forming in the meninges sclerotic and thickened plaques. After the sulci of the convexity and the anterior part of the base have been closed, the cisternæ of the base remain the only part of the subarachnoid space, within the cranial cavity, that communicates with the ventricles. Consequently, these alone will be filled up with pus. We thus get a full explanation of the pathogeny, hitherto obscure, of the posterior basic type as found in infants.

Swelling of the brain may further bring about a wedging of the oblong cord and the adjacent parts of the cerebellum into the foramen occipitale magnum. In autopsy, the wedged-in parts are separated from the rest by a marked furrow, being the impression of the edge of the foramen. The condition is associated with narrowing of the subarachnoid spaces within the wedged-in parts, and, in life, with signs of impairment of communication between the cerebral and spinal fluids. It may finally result in complete obliteration of the narrowed spaces, eventually fixed by adhesions.

According to my investigations, and contrary to the opinions expressed by many authors, the production of the fluid in the ventricles is never increased, but is lessened throughout the course of cerebro-spinal fever; the pressure of the fluid is therefore only moderately increased, normal, or even lowered. Nor have I ever found obstruction of the foramina Luschki or foramen Magendii. The above-mentioned changes, however, both constituting a consequence of cerebral œdema—i.e., obliteration of the sulci of the cerebral convexity and impairment of communication with the spinal canal, together with inflammatory changes of the membranes confining the basal cisternæ are quite sufficient to explain the pathogeny of hydrocephalus, as they all contribute greatly to impede the drainage of the ventricles.

With the progress of age, the consistence of the brain becomes more and more firm and resistant. Consequently, changes of configuration that would lead to obliteration of the cerebral sulci can develop only after a long duration. The subarachnoid spaces of the convexity thus remaining perfectly passable for a long time, are therefore the site of an active resorption of the fluid, and also of an abundant accumulation of its cellular elements. As the drainage of the ventricles is sufficient, at least in the earlier stages, hydrocephalus does not develop. On the other hand, the brain having but little possibility to change its configuration and to withdraw in that way from the pressure exercised on it by the osseous cranial walls—the pressure of the fluid is quite a different matter—suffers more through this condition, which in its turn manifests itself by violent cerebral symptoms.

In infants with their plastic brain, the cerebral manifestations are, on the contrary, quite colourless, and so the disease remains very often undiagnosed, not only by general practitioners, but sometimes even by most competent examiners. So, when J. Thomson, speaking about the posterior basic meningitis in infants, states that "in a considerable proportion of cases . . . there is a history of antecedent catarrh of the nose, bronchi, or intestines"; that "the three cardinal symptoms of the early stage are *head retraction, vomiting*, and *convulsions*," I must admit that I think there is some error in these statements, because I never saw a meningitis begin in that way, and had plenty of opportunities to meet with cases remaining undiagnosed until the third week. Thus, so far as my experience goes, the presumptive antecedent catarrh is to be regarded as the initial period of definite meningitis, and the symptoms of the supposed early stage as a condition of definitely constituted hydrocephalus. To become persuaded of the truth of this assertion, it is sufficient to determine the width of the ventricles: they are already, in the latter stage, considerably dilated, the lumen measuring about 30 mm.

The Ventricles the Essential Site of Infection.

The notion that, in cerebro-spinal fever, the ventricles constitute the only really essential site of infection is, no doubt, of great import for serotherapy, for it points out the fact that this cardinal focus must be attacked first of all by serum, the presence of serum in the subarachnoid space being without significance. In fact, we may count upon a therapeutic effect only if the concentration of serum throughout the ventricular system is so high that it lets the fluid give, with the emulsion of the autogenous strain of meningococcus, the complement-fixation reaction. This concentration must be maintained during several days until the examination of the ventricular fluids—the state of the spinal fluid is unreliable—shows absence of meningococci.

In most cases this aim is easily attained even by epimedullar administration—i.e., by injecting the serum through the lumbar puncture. Indeed, when letting out, before injection, a sufficiently large amount of fluid, injecting adequately large doses of serum, and repeating the procedure every day, we can find—using for the determination a specific anti-horse precipitating serum—the concentration of serum in the ventricular fluid, shortly after epimedullar injection, as high as about 10 per cent., and after 24 hours, before the next injection, not lower than 3, or, at least, 1 per cent. If the standard of

susceptibility, the lack of resistance of the organism, however—not its movement towards the meninges—constitutes the real reason why the general blood infection is, as a rule, of very short duration. In fact, as soon as the patient develops even the slightest degree of general immunity, the meningococci present in the circulation are impaired in vitality, lose their power to bring about metastatic lesions, and finally are completely destroyed. The former foci in the depth of the tissues disappear in a few days; and the rapid retrocession of the cutaneous changes offers us an excellent opportunity of following this process closely. Occasional metastatic lesions in the meninges, if they exist at all, must exhibit, no doubt, the same retrograde evolution, for the specific defence substances of the blood have as completely free access to these thecæ with their endothelial lining as to any other serous membrane or parenchymatous organ. Besides, whenever a certain part of the subarachnoid space—e.g., the spinal theca—is cut off from communication with the ventricles and thus ceases to be continually infected, the meningococci there disappear immediately, and the inflammation thereupon assumes a serous character. This must be regarded as the best proof that an autonomous meningitis independent of the ventricular process does not exist at all.

The conditions encountered by the infectious process in the cerebral ventricles are fundamentally different. The surface of these cavities is ontologically external, and possesses, in contrast with the meninges, not an endothelial but an epithelial lining. This layer constitutes normally for the proteins, and thus also for the antibodies of the blood, an almost impenetrable barrier; and even in the course of ventriculitis, when the inflammatory exudate carries some amount of plasma into the ventricular cavities, this obstacle is very serious. It is also of great import that this exudate is continually diluted by the cerebro-spinal fluid secreted in the ventricles. So we must conclude that the meningococci find in the cerebral ventricles extraordinarily favourable conditions for their existence, even more favourable than those upon the mucous membranes of the respiratory passages. Consequently, they can maintain themselves here for weeks, and even for months sometimes, while the continuance of any other deep infectious focus has long become quite impossible.

To emphasise that, in the above conception of meningococcal infection, we are not compelled to assume any mysterious faculty, for instance any special affinity of the meningococcus; it is sufficient to assume that it has certain properties which can be easily ascertained: (1) the ability to live in and upon the epithelial lining of the respiratory passages or of the cerebral ventricles; (2) surprising power of multiplying, but only (3) a slight power of resistance.

Course of the Disease.

In the course of the disease, three *étapes* may be distinguished: (1) meningococcal grippe, the only localisation apt to spread and to form epidemics, as pointed out by the author in 1905, and by Dopter in 1909; (2) septicæmia; and (3) choroido-ependymitis. The *étapes* do not constitute definite stages (periods), as only the second is transient, while the first and the third may last simultaneously for weeks and months. In the first, the process, affecting comparatively resistant structures, chiefly the naso-pharynx, is generally characterised by quite insignificant reactive symptoms.

When comparing systematically, during the course of cerebro-spinal fever, the fluid afforded by ventricular puncture and that obtained from the spinal theca, we soon find that the meningococci multiply principally, or rather exclusively, in the ventricles; and the spinal fluid contains only those cocci that it brought on passing from the ventricles into the subarachnoid space. In addition to this, both fluids generally differ greatly in their qualities, even in cases where there is no evidence of any serious obstacle to communication between them. Two cardinal types may be distinguished.

In the one, the reactive inflammation of the ventricles is quite insufficient; their fluid may appear quite clear to the naked eye; the white cells therein are very few, the mononuclears, lymphocytes, and epithelial cells are largely predominant or exclusively present; in short, suppuration is practically absent, and the reactive process has the character of serous inflammation or even simple irritation. Nevertheless, the ventricular fluid is sometimes directly crowded with extracellular diplococci, and the films may give the appearance of a pure culture. Now, fluid of such character is being continually evacuated into the subarachnoid space, and it is not till it gets there that definite reactive phenomena, suppuration, phagocytosis, and bacteriolysis take place to a greater or less extent. It is evident that the proper and real site of infection lies here in the ventricles, although the suppurative inflammation is completely confined to the meninges.

The other type arises in its purest form when an energetic suppuration, together with phagocytosis and bacteriolysis, has already developed in the ventricles. Films from the ventricular fluid may then exhibit almost the same picture as those from the spinal fluid. A leucocyte count, it is true, shows figures that are from several times to several scores of times as large for the spinal fluid as those for the ventricular fluid. The conclusion, however, that the leucocytes have originated from the particularly active subarachnoid suppuration, must appear erroneous, as the albumin content of both fluids is practically equal. We are compelled to admit that the white cells with their ingested meningococci have almost all come from the ventricles. Their increase in the subarachnoid space is brought about by the resorption of the fluid parts, while the cellular elements are retained by the thecal membrane acting as a filter. An identical opinion has been already expressed by Tinel as to the sheaths of spinal nerve roots, on account of the fact that, on histological examination, they exhibit no inflammatory vascular or perivascular reaction and no infectious nodules.

Explanation of the Anatomical Lesions.

All this brings us directly to the most interesting problem of the explanation of the anatomical lesions. Indeed, if cerebro-spinal fever has been hitherto regarded as a primary purulent meningitis with ventriculitis as a possible secondary, but not necessary lesion; this opinion is based upon the fact that in earlier stages of the disease the ventricular changes are often very slight and sometimes appear to be absent (to the naked eye), while thick and extensive layers of purulent exudate cover the meninges. So authors were induced to assume that this pus is formed in situ as a result of local purulent inflammation. In this supposition, however, they did not take into consideration that the ventriculo-subarachnoid system is filled with fluid which exhibits a certain current, slight, it is true, but nevertheless permanent, as it is secreted exclusively in the cerebral ventricles by the choroid plexuses, and absorbed exclusively throughout the extent of the subarachnoid space. On account of this current we are brought to consider the possibility that the pus cells found upon the meninges may sometimes, indeed, have been produced in situ, if the membrane received for absorption a fluid charged with free meningococci; but that, more frequently, they draw their origin from the ventricles or other parts of the meninges, and only settle down upon the thecal membrane as upon a filter. The largest accumulations of pus must thus arise in the areas where absorption of the fluid is most active. As of the two leptomeninges the arachnoid mater is the chief absorbent one, it will also be more affected. As regards distribution of the pus over the cerebral surface, it principally accumulates over the frontal and the anterior part of the parietal lobes, as we may suppose, because

om the fluid and from the centrifugalised deposit. he fluid often yields a more copious growth, specially when containing extracellular cocci. he puncture of the lateral ventricles may be erformed on the vertex either about 1 cm. from the nedian line, the needle being directed downwards and little outwards (vertical internal puncture), or about –6 cm. from the median line, the needle pointing lownwards and somewhat inwards (vertical external puncture). We may also puncture the inferior horn in the midst of the temporal lobe, situated behind the orbit. We then puncture, in the line drawn vertically through the external auditory meatus, or somewhat behind, and several millimetres above the upper edge of the pinna; we direct the needle so that looked at from the front it appears to point towards the palpebral cleft (temporal puncture). The depth of the puncture measures in the vertical procedure somewhat more, in temporal puncture somewhat fewer, millimetres than the centimetres which go to the circumference of the head. The needle—charged with its brass wire, in order not to be obstructed by brain substance—should be thrust in very slowly, millimetre by millimetre, and the wire withdrawn after each advance. The depth at which the fluid begins to flow is noted; then, on continuing to thrust in the needle, the second depth at which the flow ceases. The difference of the two figures corresponds to the lumen of the ventricle along the puncture line. Normally, this lumen measures several millimetres; a lumen narrowed (possibly to complete closure) is a sign of cerebral œdema; on the other hand, enlargement can be thus followed by us closely from the beginning in the cases developing hydrocephalus. The secretion of cerebro-spinal fluid may be determined directly when, after the pressure has been brought down to the zero point, the fluid is tapped out of the ventricles for an hour or two, the amount withdrawn being noted after each interval of five minutes.

Albumin Content of Ventricular and Spinal Fluids.

The albumin is estimated by means of Mestrezat's diaphanoscopic method. The albumin content of the spinal fluid is almost always higher than that of the fluid tapped from the ventricles. The ratio of these two values has been termed by me the "albumin index." If it is higher than 5 (5 : 1), we can assume a stasis of the fluid within the spinal space as the result of impaired communication with the ventricles. If it is lower than 2, the closing of the cerebral sulci would be the cause, the current of the fluid then trending almost exclusively towards the spinal space, and the fluid being there absorbed quickly and thus having no opportunity to charge itself with greater amounts of albuminous exudate. Middle values, 2–5, are found when no such disturbances are present or when their effects counterbalance one another. Low albumin content of the ventricular fluid—e.g., 0·01 per cent.—may be further regarded as a sign that the current within the ventricles is very active. This occurs when the lumen is narrowed and the secretory function of the choroid plexuses but moderately affected. In such cases we also find that after intraventricular serum injection the albumin standard of the ventricular fluid diminishes very rapidly. The concentration of the injected serum in the fluid may be determined with approximate exactitude by using a specific rabbit serum precipitating the horse serum. In addition to this the complement-fixation reaction is performed in a series of dilutions by using as antigen the strain cultivated from the patient. To carry out all these investigations at least 6 c.cm. of each fluid are required.

THE TREATMENT OF INEBRIETY AND DRUG HABITS.

By STANFORD PARK, M.B., Ch.B. Edin.,

RESIDENT MEDICAL SUPERINTENDENT, BAY MOUNT SANATORIUM, PAIGNTON.

About two years ago I published[1] a few comments on the treatment of inebriety and drug habits, and some later notes may now be of interest. The subject of temperance has attracted a great deal of attention from our legislators and a section of the public for many years, but, from the medical side, as far as treatment and cure of inebriety are concerned, very little has been done. A step forward was taken when it was realised that inebriety can be a disease as well as the result of weak will and wickedness.

Up to the present no specific for the disease has been found. The only definite line of treatment which has met with any degree of success has been the McBride method, employing atropine and strychnine. The chief alternative to this method has been the confinement of the patient for a considerable period in the hope that the drink craving would die down. The hope has proved futile. Patients under restraint without treatment almost invariably relapse as soon as they regain their freedom. The atropine treatment has given moderate results in a certain type of case and is still used in many homes, mainly, one fancies, for want of a better. Personally, I found, after fair trial, that this treatment and its various modifications was not a cure, and only a help in certain cases.

After trying many drugs, and with the assistance and advice of Dr. Harrison Martindale, I came to the conclusion that three substances were certainly of value used hypodermically. These were strychnine, 1/60 gr., twice daily; colloidal gold (sterules), 1 c.cm., three times daily, and calc. glycerophos., 2 gr., in 3 c.cm., 1·5 c.cm. once daily. Given by the mouth, in frequent small doses, I found the following all extremely useful: nux vomica, cinchona, kola, damiana, and gentian. Nux vomica by the mouth often gives better results than strychnine hypodermically. The following doses are best: Tr. nux vomica, 1 to 3 ♏; tr. kola, 10 ♏; tr. cinch. co., 10 ♏; ext. damian. liq., 10 ♏; inf. gent. co. conc., 12 ♏. These are best given, with ext. glycyrrh. liq., 5 to 10 ♏, in a teaspoonful of water, every two hours from 8 A.M. to 8 P.M. The nux vomica can be increased or reduced according to indications, and the same applies to the damiana, which is most useful in certain cases. Ammon. brom., 4 gr., and pot. brom., 1 to 2 gr., may be added at first, if indicated. I also found that Catha (5 gr. tablets Martindale's ext.) removes the craving for alcohol and morphine and the depression attending their use in a remarkable way in many patients. Its action is somewhat similar to that of caffeine. Other drugs proved of this serum is 1000—i.e., if the serum gives with the patient's meningococcus strain the complement-fixation reaction still in a dilution of 1 : 1000—the curative power of the ventricular fluid shortly after injection may be designated by the figure 100, and 24 hours later by 30 or 10. The sufficient intensity and continuousness of serum action is thus fully realised.

---

[1] The Lancet, 1922, i., 691.

In other cases this realisation may be difficult to obtain when the serum is of low standard, or there are obstacles on its way from the spinal space to the ventricles. The greatest difficulties arise, however, in case of narrowing of the lumen of the ventricles in consequence of cerebral œdema. If so, the serum injected epimedullarly does not penetrate into the cranial cavity, or at least, not into the ventricles immediately after injection. The up and down motion of the fluid which—apart from the abovementioned current going from the ventricles to the subarachnoid space—exists between the cranial cavity, including the ventricles and the spinal space, and might be able to bring by degrees the serum, present in the latter space, into the ventricles is very active only in normal or slightly changed conditions. Here, as the range of the modifications of volume of the brain dependent on the incessantly varying quantity of blood in the vessels is considerably diminished, owing to the state of œdema and compression, this up and down motion of the fluid must be very slight too. Moreover, the current of the fluid, though secreted in lessened quantity by the affected plexuses, must, in the narrowed ventricles, be much more rapid than usual, and oppose the penetration of the serum. The great importance of the latter factor appears quite clearly when the serum is injected, in such cases, into the ventricles themselves, bilaterally, by means of temporal puncture, and the ventricles thus filled up with almost undiluted serum. In an hour and a half the concentration of the serum in the ventricles may fall as low as 3 per cent., and in eight hours or perhaps sooner reach the level at which its therapeutic action ceases completely. We should then be obliged, if these procedures are at all practicable, to repeat the intraventricular, bilateral injections, at equal intervals, several times daily; or else to wait until, with the impairment of drainage, the ventricles become markedly wider, and thus the conditions for epimedullar or, at least, intraventricular serum administration, more favourable.

Immunisation.

Similarly to the passive immunisation brought about by injected serum, the active immunity developing spontaneously or under the influence of vaccine treatment can only then react on the infectious process if the antibodies appear in sufficient quantity in the ventricular fluid. The albumin standard of the ventricular fluid is generally very low—e.g., 0·02 per cent. This would correspond to a plasma content of 0·22–0·24 per cent., or to a dilution of plasma, when passing with the inflammatory exudate into the ventricular cavity, of about 1 : 400. In such a case the therapeutic power of the patient's serum should be as high as 400 in order to reach the limit of activity within the ventricular cavities. The ability to acquire sufficient general immunity varies largely in different individuals. Some react very promptly and efficiently under the sole influence of the morbid process, while the others do not exhibit any immunisation which could be revealed by the complement-fixation or other serum tests, even after long treatment by autogenous vaccine.

In one of my cases, that of a boy aged 5, who had been insufficiently treated with intraventricular serum injections, a relatively high general immunisation was obtained by the vaccine injected at about weekly intervals rising from the initial dose of 200 millions to the dose of 30,000 millions of cocci, every dose being divided into from 10–40 smaller ones, injected separately under the skin. The value of the patient's serum, determined by complement-fixation reaction, finally oscillated between 100 and 300. The infectious process showed a marked improvement, but exhibited no tendency to definite cessation, and fluids, especially the ventricular fluids, continued to yield an abundant culture. There was an irregularly remittent pyrexia with elevations up to 40° C.; 16 c.cm of the patient's serum, freshly prepared, consequently working also as complement, were then, on the ninety-second day of the illness, injected into the right lateral ventricle. Immediate and complete recovery followed.

Apart from general immunisation, perhaps also some local processes—suppuration or local neutrophilic leucocytosis, local basophilia and eosinophilia, and possibly local production of antibodies—coöperate in combating the infection.

On the other hand, it is a well-recognised fact that suppuration becoming excessive and leading to accumulation of thick pus in the ventricles and the subarachnoid space is one of the causes of fatal issue. It is noticeable that, in these progressively purulent cases, the fluids, both ventricular and spinal, give with the autogenous meningococcus culture a marked complement-fixation reaction, sometimes in high dilutions. Specific serum is generally of no effect in this condition.

Technique of Ventricular Puncture.

To conclude, some words about the technique adopted for the investigations and procedures. As the ventricles form the cardinal site of the infectious process, the examination of the spinal fluid alone is evidently quite insufficient and apt to give a distorted idea of the true bearing of the case. Coincident examination of the ventricular fluid is most desirable if only for practical purposes, and thoroughly indispensable when scientific aims are at stake. So it has gradually become my habit to perform always, on principle, one after another both the lumbar and ventricular punctures; sometimes the puncture of the subarachnoid space of the brain was also performed, and yielded a third fluid for examination. The ventricular puncture is a slight operation easy to perform, not only on infants when we can enter the cranial cavity through the anterior fontanelle, but also on patients of any age when using the channel-borer devised by Goetze for piercing the cranium. This borer is only 1½ mm. thick. Its channel serves to introduce into the bore-hole, before the borer is drawn out of it, the glazed brass wire stretching out of the puncturing needle, and well adapted to conduct the needle afterwards into the bore-hole. The needle is 1 mm. thick, and ought not to be too sharp. No anæsthesia, either general or local, is necessary. The patients usually state that the operation gives them much less pain than the lumbar puncture. Every time a new bore-hole must be made. The procedure is quite safe; I have performed it over a thousand times since the year 1914. The pressure is always determined, as well for ventricular as for lumbar punctures, in a strictly horizontal position of the patient in order to obtain some inkling as to the possible impairment of communication between the cranial and spinal spaces. The number of white cells per c.mm. is estimated by means of the Fuchs-Rosenthal chamber, and the differential leucocyte count, executed in centrifugalised deposit films, dyed with phenol toluidine and Jenner's stain. The basophiles and eosinophiles are thus also kept under observation. They are generally quite absent in fatal cases; in moderately severe ones, rare at the onset, they become more numerous with the progress of improvement, but are most numerous in cases of spontaneous recovery, particularly at the moment of recovery, and may be met with for months afterwards, sometimes in considerable quantities. The number of meningococci per 100 white cells is estimated in toluidine-stained films and calculated per c.mm. The percentage of (1) intracellular, (2) extracellular cocci, and (3) organisms contained in epithelial cells is determined, and, on the other hand, the proportion of (1) well-preserved, and (2) altered cocci. Cultures are made escaped altogether, seems to emphasise the infectious or contagious character of the outbreak.

There has been little to aid us in fixing the incubation period. One boy was isolated on July 9th with fever and a sore-throat, and when Koplik spots appeared on the 11th he was moved into a sick room which had been vacated some hours previously by two boys who had recovered from epidemic pleurisy. He went through a mild attack of measles, and on July 17th, after several days of normal temperature, became feverish again with left pleurodynia. Next day a well-marked rub was heard. If the disease in this case was caused by direct contact with other boys the incubation period cannot have been less than eight days, but, of course, it is possible that the room or its contents conveyed the infection.

Unlike the Paddington Green cases, the illness often began or was accompanied by a sore-throat, sometimes simply a red granular pharyngitis, sometimes a definite follicular tonsillitis. In 27 of these 48 boys a well-marked throat lesion was noted. Swabs were taken of some of them, and there was reported a free growth of streptococci, with fewer colonies of *Staphylococcus aureus* and no diphtheria bacilli.

Another difference from the Paddington Green patients is that they never, with one possible exception, really suggested a pneumonia. Some were worse than others, but in no instance was the boy very seriously or acutely ill. In fact, it was remarkable how little constitutional disturbance there was in most of them. Even with a temperature of 103° or 104° F., and a loud rub, there was generally comparatively little distress. Cough was conspicuous by its absence, and there was never any sign of involvement of actual lung tissue.

In all cases there was more or less severe pleurodynia, but in only 17 out of the 48 did we satisfy ourselves that we heard a pleural rub. When a rub did appear it was often very loud indeed, and some patients could themselves feel or hear the creak at the end of inspiration, often long after it had ceased to be acutely painful. A marked feature was the liability to relapse, each rise of temperature being accompanied by the appearance of a fresh patch of pleurisy, three or even four relapses having occurred in some cases. No case had any signs of an effusion. Joint pains and albuminuria were absent. Apart altogether from relapses, many of these boys took a long time to get well, and some became anæmic and debilitated and had to be sent away on sick leave.

It is noteworthy that we have seen during the last few months several cases of a similar nature in patients in the immediate neighbourhood, apart from the epidemic in the school.

A governess and three children, aged 3 to 7 years, had simultaneously attacks of pyrexia. The governess had severe pleurodynia and the children complained of abdominal pain. In none of them could we detect a pleural rub, but they all relapsed, and clinically appeared to be identical with the cases we were seeing at the same time in the school a mile away.

A hospital nurse was admitted to the ward with pyrexia and abdominal pain, which at first suggested the diagnosis of acute appendicitis. Within a few hours, however, the temperature fell and the pain became confined to the chest and was only felt on deep inspiration.

A motor driver complained of pain in his side; temperature 100° F. There was a definite pleural rub. On the eighth day the physical signs had disappeared and he was apparently quite well again.

In conclusion, the facts suggest that we have been dealing with an infectious disease, showing a predilection for children and young adults, and manifesting itself clinically by producing a primary inflammation of the pleura. The frequency with which inflammation and infection of the tonsils and pharynx were associated with the onset of the illness suggests that the throat was the site of entrance of the causative organism. Whether the streptococcus which was isolated from the fauces in a few cases was in any way responsible for the epidemic it is impossible to say without further investigation. If we consider rheumatic fever as an acute inflammation of serous membranes usually preceded by a tonsillar or pharyngeal affection, with a tendency to occasional epidemic prevalence, a possible relationship between the two diseases suggests itself.

A CASE OF

HORIZONTAL DILATATION OF THE LEFT AURICLE.

BY H. BATTY SHAW, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

THE following case is similar to that first described in 1901 by Sir Isambard Owen and Dr. W. J. Fenton.[1]

Miss X., aged 26, was first seen in consultation with Dr. C. H. A. Alderton on June 12th, 1921. The matter in debate was whether she was fit to marry, seeing that she had a cough and was very short of breath and had so much pain in the region of the heart. She was known to have had pneumonia and pleurisy at the age of 12, and rheumatism of the heart at the same time. On examination she was found to have the maximum impulse of the heart in the fifth left interspace, well outside the mid-clavicular line, and murmurs were heard at this spot, indicating double mitral disease; the heart was not enlarged to the right. There were signs of consolidation at the left base behind, which explained the cough and yellow expectoration. As the heart-rate was rapid and irregular, she was diagnosed as a case of double mitral disease, auricular fibrillation, and pneumonia. There were no tubercle bacilli in the sputum.

She was not seen again until March 23rd, 1923, when again shortness of breath had become very severe, and she had expectorated about 4 oz. of blood about one week previously. She was also troubled with palpitation. On examination the impulse of the heart was found to be displaced to the left as before, but the mitral murmurs were not so audible. In addition, a large area of dullness had developed to the right of the middle line, which was continuous with the cardiac dullness, reaching up to the third right intercostal space, and well outside the right mid-clavicular line. In the third space the dull area revealed a well-marked systolic murmur and there was distinct pulsation in the same space outside the mid-clavicular line. The spleen was enlarged and readily palpable, and there was increase of the liver dullness two-fingers' breadth below the right costal margin. The diagnosis made was horizontal dilatation of the left auricle to the right, following Sir Isambard Owen and Dr. W. J. Fenton's description in 1901 of the first case.

She was admitted to University College Hospital on March 28th, 1923. To her former symptoms there was added a new one—namely, that after swallowing food pain developed in the right chest, lasting for about a minute. Her nutrition was defective; although her height was 4 ft. 9½ in., she only weighed 5 st. 9 lb. The dullness to the right of the heart was as extensive as before, and pulsation was now felt in the fourth and fifth right spaces as well as in the third and outside the mid-clavicular line. A systolic murmur could be heard at the apex, which was quite distinct from the systolic murmur heard over the area of dullness and pulsation of the right chest. The patient was a little cyanosed and became easily breathless on exertion; there was no ascites or dropsy; the urine was free from albumin; the temperature was normal; the pulse on admission was 100, and on discharge—after 12 days—had reached about 80: the blood pressure was 124 mm. Hg: there was no clubbing of the fingers.

X Ray Report by Dr. R. W. A. Salmond.

This was carried out on March 30th, 1923, and is as follows:—"On the right side of the chest there is a large rounded shadow which shows a pulsating upper margin but no pulsation on its lower margin. This shadow shows more density than the enlarged left side of the heart. In the lateral view the shadow on the right side extends backwards nearly to the spinal column, and is pressing on the œsophagus, so that when a barium feed is given it is definitely held up at the upper margin of the shadow. In addition to the compression of the œsophagus, the trachea and bronchi are displayed to the right. The amount of pulsation seen on the upper margin of the shadows of the right and left sides of the chest is against the shadow being that of a pericardial effusion. There are no obvious signs of disease in the lungs, and no signs of pleural effusion."

---

[1] Clinical Society's Transactions, 1901, xxxiv., p. 183.

use in some cases. Various hypnotics must be used, and the most useful are chloralamide, methylsulphonal, and luminal. In drug cases sulphonal is often best. One can give up to 75 gr. of chloralamide and 60 gr. of methylsulphonal. When one drug alone fails, an excellent night's sleep is often obtained by giving a dose of the second three hours after the dose of the first drug. Chloralamide is safe, and can be given to patients in very poor health.

With regard to general treatment, ambulatory treatment nearly always fails and institutional treatment is essential. It is found also that patients do better in a small than in a large institution. In a large one they are apt to split up into cliques, and a drinking clique is formed whose members only wish to be patched up preparatory to starting another drinking bout. They have no intention of remaining cured, and are apt to lead other patients astray and introduce secret drinking into the establishment. In a small home patients are more under the direct observation of the doctor, and the moral influence is greater. It is advisable to place patients on parole after the first week or so. When they know they are trusted they seldom break their word, and if they do it is easily noticed in a small home that they have taken alcohol, and parole can be withdrawn.

In treating this class of case it is not only a question of what drugs to use, but also how to use them, and there is no doubt that the successful treatment of inebriety depends a good deal on the experience of the physician and the technique employed. Undoubtedly the manner of withdrawal of the stimulant is a very important point. As Dr. F. Hare has shown, nothing is to be gained, and frequently a great deal is lost, by a sudden withdrawal. From the third to the sixth day onward direct suggestion, applied in the hypnoidal state, is useful in many cases. At times sleep can be produced by it without the use of hypnotic drugs at all.

Results.

That treatment on the above lines is effective has been proved by the past few years' results at Bay Mount. Out of all cases treated between September, 1922, and September, 1923, in which a favourable prognosis was given before treatment was commenced, 92–3 per cent. have remained teetotal for from five to 17 months, and are still abstainers. In case it is suggested that this high percentage of successes is due to the exclusion of all except the mildest cases, I indicate the points which decided classification.

1. *Heredity.*—Patients with a history of insanity in the family were excluded, but an alcoholic ancestry of itself did *not* lead to exclusion.
2. *Health.*—Patients were excluded who were suffering from any disease which might drive them to drink.
3. *Age.*—Patients over 55 years were excluded, if the habit was of long standing.
4. *Unwilling Patients.*—A patient who came against his will, or to please his relations only, was excluded.

Apart from patients excluded for the above reasons, severe and chronic cases were included. If we take cases in which a good prognosis was not given, we find that over 50 per cent. of these have remained teetotal to date. When it is explained that several cases are included in this class who, for business or other reasons, did not complete the treatment, the results are even better than the figures indicate. I append three examples of cases in which a good prognosis was given, and three in which it was withheld.

1. Male, aged 52, had been drinking over a bottle of whisky daily for several years. Father a moderate drinker, grandfather a heavy drinker. Patient depressed, tremulous, sleeping badly, and appetite moderate. Blood pressure 160. Urine, trace of albumin. This patient did well, and left in better health than he had enjoyed for over five years, and has remained teetotal over 15 months.

2. Male, aged 48, had been drinking to excess since 1914; a few days' moderate drinking, then 48 hours' heavy drinking, then an abstainer for about three weeks. Father drank heavily for years. Several brothers also drank to excess. Patient very nervous, sleeping badly, and appetite poor. Blood pressure 132. Urine normal. After treatment patient had no desire at all for alcohol at his usual time for craving, and left in excellent health. He has remained teetotal for 12 months.

3. Female, aged 35, married. She had taken alcohol in moderation for some years, but after marriage some five years ago she began to drink to excess when alone, and gradually got to over a bottle of whisky a day. Had atropine treatment a year ago without benefit. Father and mother took a good deal of alcohol. Patient in fairly good condition, but not sleeping well. Blood pressure 125. Urine normal. Patient did well, and left in excellent health without any craving, and has remained teetotal to date, 11 months.

Bad prognosis cases:—

1. Female, aged 55, married, had been drinking steadily for over 15 years, taking one and a half bottles of whisky a day. Father and brother both drank to excess. Patient very thin, tremulous, and sick in the morning. Appetite small. Patient spent much time in bed and had no interest in life. Blood pressure 156. Urine normal. She did well under treatment, gaining 12 lb. in weight, and lost all craving, and took an interest in life again, getting up for breakfast and staying up all day. Husband reported 12 months after that she was teetotal and taking great interest in her home.

2. Male, aged 57, single, had taken alcohol all his life, but was teetotal from 1899 to 1905. Since then had been drinking steadily to excess. Mother mentally weak, and one brother died from drink. Patient very energetic, playing games all day long. He sleeps well, eats moderately well. Very tremulous and obviously eccentric and excitable. Under treatment he lost all desire for alcohol and left in good health, having lost his tremor, and has remained teetotal to date, 12 months.

3. Female, aged 56, widow, a notorious drunkard, who had had treatment many times in various establishments. She had been drinking heavily for years, breaking out every two or three weeks. Family history nothing to note. Patient had chronic bronchitis and was sleeping very badly. Appetite was small and capricious. Blood pressure 182. Traces of albumin in urine. Patient left after six weeks' treatment, having lost all desire for alcohol, and sleeping pretty well and eating well, and able to walk two miles. Has remained well and teetotal ten months to date.

Under this method of treatment, apart from a cure, patients get over the acute symptoms of alcoholism in a remarkable way. Usually within seven days they sleep six or seven hours at night, eat very well, and have lost all tremor, and, in fact, show very few outward symptoms of their drinking bout.

Clinical and Laboratory Notes.

EPIDEMIC PLEURISY.

BY W. ATTLEE, M.D., B.CH. CAMB.,
A. M. AMSLER, M.B., B.S. LOND.,
PHYSICIANS TO KING EDWARD VII. HOSPITAL, WINDSOR, AND MEMBERS OF THE ETON COLLEGE MEDICAL BOARD;
AND
D. C. BEAUMONT, M.B., B.CH. CAMB.,
ASSISTANT PHYSICIAN TO THE SAME HOSPITAL.

AN outbreak of this affection occurred in Eton College in May, June, and July of this year. In many respects it was very similar to that described in THE LANCET of July 12th, 1924, as having occurred in the country branch of the Paddington Green Children's Hospital last May. Curiously enough, these two institutions are not more than a mile apart, but, so far as we are aware, there is no intercommunication or connexion between them.

In all, 48 cases came directly under the care of one or other of us, but other cases, in addition to these, occurred in the school. The first began on May 11th and the last on July 15th. All the patients were boys of 14 to 18 years of age. They were scattered irregularly throughout the school, but the fact that some houses had as many as six cases, while others uterus. Behind its entry into the uterus the latter presents a bulging swelling which has ruptured and from which projects chorionic tissue. Attached to this and overlying it was a mass of chorionic tissue, forming the wall, a third of an inch thick, of a cavity about one inch in diameter. This cavity is lined by a smooth membrane and from its interior projects a thin filament, probably the umbilical cord. The uterus measures four inches by four. On section there is found to be an intra-uterine pregnancy containing an embryo about half an inch in length. The left Fallopian tube and ovary, which appeared healthy, were not removed.

Remarks.

This specimen is of interest because it exemplifies a comparatively rare condition known as tubo-uterine or interstitial gestation, and also a much rarer condition—viz., a concurrent intra-uterine pregnancy. The uterine fœtus appears to be about six weeks old, and one is led to speculate whether the two pregnancies took place at the same date. The specimen was sent to the Royal College of Surgeons Museum, and the illustrations are by Mr. S. A. Sewell.

AN UNUSUAL REFERRED PAIN IN A CASE OF CHRONIC APPENDICITIS.

BY SIR BRUCE BRUCE-PORTER, K.B.E., C.M.G.,
M.D. BRUX., M.R.C.S. ENG.

THE following case is published in view of the unusual situation of the referred pain.

L. S., aged 51, consulted me for pain in the right chest over the nipple area. The pain came on originally in 1919, and was very severe. He consulted a physician in Manchester, who suggested angina as a cause. He was next seen by a heart specialist in London, who also suggested angina and advised rest. He was given eight weeks' rest in bed, and, being no better at the end of this time, consulted an osteopath. After some treatment from him he felt better and remained so for a year. A return of the pain again sent him to a heart specialist, who advised Nauheim treatment for it, and he had 12 weeks at Spa with no improvement. He then consulted another physician in London, who suggested duodenal ulcer, and put him on strict diet for many weeks. There was no improvement, so he returned to the osteopath. Being no better, he next sought the advice of a surgeon, who took the view that he suffered from duodenal trouble or gall-stones and advised a period of diet, to be followed by operation if no improvement took place.

On July 4th of this year he consulted me. The heart sounds were normal and the blood pressure 120 maximum and 70 minimum. In pinching up the skin of the abdomen there was definite resistance over the appendix area, but nowhere else. Pressure over the appendix at once caused the patient to cry out, and place his hand over the right nipple area. He said, "Why, that is my pain," and each repetition of the pressure produced an exacerbation of the pain. There was a history of digestive troubles in childhood and during early manhood. I advised early exploration and removal of the appendix, after a very septic condition of the teeth and gums had been cleared up.

Operation.—Sir Alfred Fripp opened in the middle line, and, before removing the appendix, investigated the stomach, duodenum, and gall-bladder. There was no evidence of old or recent ulceration; the stomach was normal in size and the gall-bladder empty. The appendix showed evidence of old and recent inflammation, and there were a few adhesions in the pelvic region. The appendix was removed and the wound closed.

When the patient recovered from the anæsthetic the first thing he noticed was the absence of the pain, and it has not returned. He is now eating ordinary diet, and the change in his appearance is remarkable, for with so many different opinions he had made his own diagnosis of cancer, and removal of this fear has changed his whole mental outlook. Years ago I had a case of a somewhat similar character in which the pain was over the left nipple area. The patient, a young officer, had consulted me for heart disease, and, having in mind the old saying, "If a man complains of his heart think of his stomach," investigation of his digestive region soon revealed a chronic appendix, removal of which at once relieved the præcordial pain.

Reviews and Notices of Books.

REJUVENATION AND THE PROLONGATION OF HUMAN EFFICIENCY.

By Dr. PAUL KAMMERER. London: Methuen and Co., Ltd. 1924. Pp. 252. 8s. 6*d*.

THE subject of rejuvenation and the question whether human efficiency can be prolonged by artificial means are of overwhelming interest to the outside public as well as to the medical profession. The search for the elixir of youth is an old one, and the press has not been slow to seize on and to exploit the dramatic interest of Steinach's work. As a result much misrepresentation has occurred, with consequent discredit to what is undoubtedly a praiseworthy piece of physiological research. A book suitable for the general public, which conveys the limitations as well as the possibilities of Steinach's method of rejuvenation, should thus prove of service. Dr. Paul Kammerer has collaborated with Steinach in the past and has an intimate knowledge of his work and personality. His exposition of the subject includes a consideration of the processes of ageing, a brief survey of the part played in these processes by the endocrine glands, and of the results obtained in the laboratory from ligature of the vasa of aged rats. Dr. Kammerer then proceeds to record the results obtained in human beings. He is of the opinion that already sufficient evidence has accumulated to allow of a favourable verdict being given, although with Harms he is prepared to reserve opinion as to whether the operation can affect exhausted nervous tissue. His view is that rejuvenation must act by making it possible for a man to die from normal senility, whereas according to Nothnagel's estimate only 1 in 10,000 dies from such a cause. So confident is he of the genuine nature of the results obtained from vaso-ligature in the human being that he considers it worth while to discuss such questions as the morality of the proceeding and its effect on the community. Surely such questions are a little premature? Whilst we are prepared to admit the interest of Steinach's research, we can hardly feel satisfied, as Dr. Kammerer appears to feel, that the operation as applied to man has already justified itself. On the whole, although instances of decided improvement following the operation have been recorded, the results in man have been far less striking than those obtained in rats by Steinach at Vienna, and Machts in America. We must therefore remain amongst those "super-cautious people" mentioned by the author, who hesitate to generalise hastily. On the whole, however, Dr. Kammerer has given a fair and restrained review of the subject.

OPERATIVE SURGERY.

By WARREN STONE BICKHAM, M.D., F.A.C.S., former Surgeon in Charge of General Surgery, Manhattan State Hospital, New York; former Instructor in Operative Surgery, College of Physicians and Surgeons (Columbia University), in the New York Post-graduate Medical School and Hospital, and in the New York Policlinic Medical School and Hospital. Vol. III. London: W. B. Saunders Company, Ltd. 1924. Pp. 1001. 50s.

THE third volume of this large work resembles in scope and arrangement the two volumes already published. Unlike many treatises on operative surgery, it contains full descriptions of operations upon the ear, nose, throat, and eye. The author explains in his preface that in including these he hopes to assist those practitioners whose work lies in centres where specialists are not available. Besides an account of these special subjects this book gives descriptions of operations upon the head, neck, and thorax, so covering extensive ground. Many procedures are described which are not to be found in the usual text-books of operative surgery, and the surgeon who consults this work will get assistance in

The patient was discharged from the hospital, but died on Jan. 11th, 1924, and it was then confirmed by post-mortem examination that the dull area of the right chest which revealed pulsation and systolic murmur was due to a greatly and horizontally dilated left auricle, the chamber containing 1½ pints of blood.

Post-mortem Examination by Mr. W. G. Barnard.

"There are general hypertrophy and dilatation of all the chambers of the heart, which measures 7½ × 8½ × 4 in. The left auricle is dilated out of proportion to the other chambers, and at the post-mortem examination held 30 oz. of blood; it measures 5½ × 7 × 4 in. and extends laterally from the hilum of the left to the hilum of the right lung and from the arch of the aorta above, to within two inches of the apex of the heart below. The arch of the aorta and the bifurcations of the trachea have both been displaced upwards. The pressure collapse of the free border and lower lobe of the right lung can be seen. The parietal and the visceral layers of the pericardium are adherent universally. There are considerable thickening and rigidity of the free borders of the mitral valve which have fused to form a crescent-shaped opening which will barely admit the tips of two fingers." Microscopic sections of the wall of the left auricle failed to show the presence of any organism.

Comment.

The original account of this condition made a clinical diagnosis possible, for it clearly showed that the left auricle is capable of dilating horizontally to the right, and capable of producing dullness to percussion and pulsation in the upper and outer part of the front of the right chest. Another fatal case producing similar dullness was described by Dr. J. G. Emanuel[2] in March of last year.

I have under observation another case seen with Dr. C. Wyndham Gittens occurring in a woman, aged 60 years, who during the earlier stages of the malady, whilst under observation at the Brompton Hospital, showed by X rays (Dr. Stanley Melville) a limited dark area to the right of the cardiac shadow which I concluded was due to mediastinal growth; later on the above-mentioned dark area gradually increased in size, according to X ray examination. Quite recently it was possible to notice dullness to percussion reaching continuously from the heart outwards beneath the right pectoralis major, the upper margin of which was the third rib, and in the fourth intercostal space beneath the same muscle pulsation could be defined, synchronous with the apex beat; the pulsation reached into the right axilla. The Wassermann test was negative, and although it is impossible to find a history of rheumatism, or signs of mitral disease, it seems very probable that this patient is also suffering from horizontal dilatation of the left auricle to the right border of the chest.

RUPTURE OF TUBO-UTERINE GESTATION,

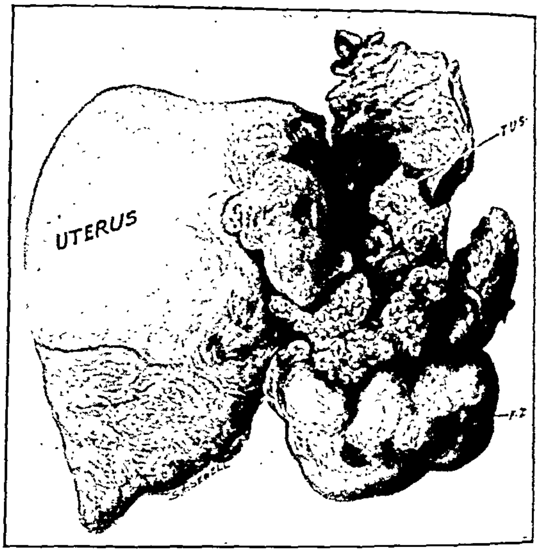
WHICH WAS CONCURRENT WITH INTRA-UTERINE PREGNANCY.

BY W. GIFFORD NASH, F.R.C.S. ENG.,
SURGEON TO THE BEDFORD COUNTY HOSPITAL.

I HAVE now met with three instances of tubo-uterine gestation. The first patient,[3] in whom the sac had been ruptured three days, died after hysterectomy. The other two recovered. In the second case[4] I was able to resect the sac and save the uterus. A year later this patient had a normal labour. The following is a record of the third case:—

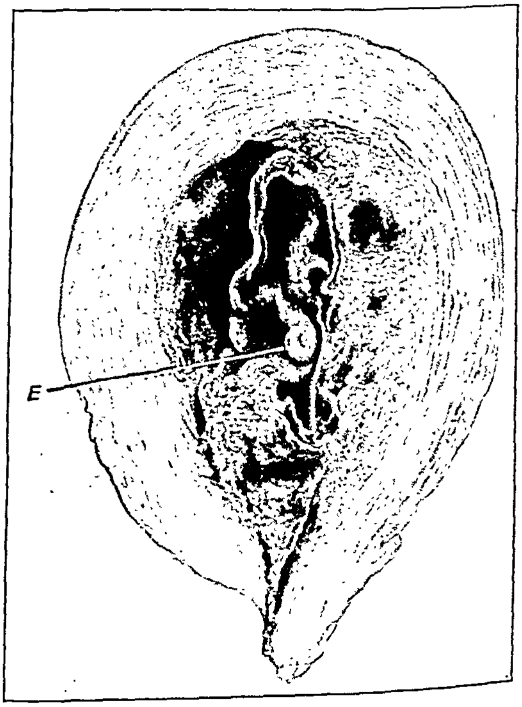
Mrs. A., aged 31, was admitted to the Bedford County Hospital on June 12th, 1923. She had two children, aged respectively 3 years and 13 months. Nine weeks had elapsed since her last period. On June 11th she had a sudden attack of severe pain in the right lower abdomen, followed by nausea, vomiting, and fainting. On admission to hospital she was very collapsed with a pulse of 136. The abdomen was distended and rigid. Immediate operation was decided on and a medium incision was made below the umbilicus. There were much blood and clots in the lower abdomen. A ruptured sac with projecting membranes was found at the right upper corner of the uterus, and this occupied so much of the uterine wall that it appeared impossible to excise it. Supravaginal hysterectomy was performed. Recovery was delayed by a *B. coli* infection of the right kidney, which necessitated residence in hospital for eight weeks.

FIG. 1.



Showing wall of tubo-uterine sac and chorionic tissue.
T.U.S. = Tubo-uterine sac. F.T. = Fallopian tube.

FIG. 2.



Longitudinal section of the uterus showing fœtal membranes and embryo (E).

Description of Specimen Removed.

The uterus is irregularly enlarged to about the size of a ten weeks pregnancy. The right ovary appears to be normal. The right Fallopian tube is rather short and thick and can be traced entire up to its junction with the here brought together, giving all the most modern methods and representing a huge amount of work of the highest class. The question of a developmental cycle of the spirochæte is discussed, especially the phenomena of granulation, and the author contents himself with setting down the evidence and leaving the question undecided. The same is true of the question of a neurotropic strain of the organism. The complement-fixation test is discussed fully and fairly, and its significance and limitations pointed out. The precipitation test is also exhaustively dealt with, with special reference to the Sachs-Georgi test. The chapter on the cerebro-spinal fluid by Dr. Cruickshank is well written and gives concisely modern methods of examination and interpretation. The chapter by Dr. Taniguchi on the nature of the syphilitic antibody is admirable and stimulating.

---

[2] THE LANCET, 1923, i., 591.
[3] THE LANCET, 1905, ii., 593.
[4] Ibid., 1917, ii., 122.

The second part of the work on treatment is sound and moderate in tone, making no fantastic claims for results. Dr. Mackenzie gives fully the scientific data that led up to the use of salvarsan remedies, and enters fully into the question of untoward results of its administration. The author appears to under-estimate the results to be expected from the treatment of tabes, and gives little hope of any effect of treatment of general paresis. No mention is made of the malaria treatment. It is matter for regret that the writer has not devoted a chapter to the use of bismuth, which has now a definite place in therapy of syphilis alongside salvarsan derivatives and mercury. A fuller discussion on tests of functional liver inefficiency, in the attempt to avoid destruction of liver cells by the arsenical preparations, would also have been welcome. The introduction to the work by Prof. Muir is an admirable piece of writing—a monograph in itself, completing an excellent scientific treatise which reflects credit on the authors and their collaborators. In the list of references no recent article of value in the realm of syphilis seems to have been omitted.

Every clinical and laboratory worker in syphilis should buy this work, read it carefully, and then keep it for reference.

ÉTUDES MÉDICO-CHIRURGICALES SUR LE DUODENUM.

By PIERRE DUVAL, JEAN CH. ROUX, and HENRI BÉCLÈRE. Paris: Masson et Cie. 1924. Pp. 269. Fr.35.

THE duodenum and the viscera in close relation to it constitute a field of growing importance to the surgeon and radiologist, and Duval's clinic affords an unparalleled opportunity to both. The radiologist particularly will welcome the work under review, and if it does not solve all the problems that an attentive study of this region provides, it will certainly help the observer to systematise his ideas.

The book deals with the following subjects: (1) The duodenum in biliary lithiasis; (2) stenosing idiopathic periduodenitis; (3) compression by the mesenteric pedicle; (4) duodeno-jejunostomy; (5) duodenal ulcer; and (6) intoxication in duodenal stasis. Each section is well worked out in considerable detail. Forty pages, for example, are given to the subject of compression by the mesenteric and middle colic arteries. The diagrams and descriptions of this condition and of the operations undertaken for its relief are clear and useful. The section on ulcer follows Akelund's work in its general lines. The skiagrams made by the serial method are well reproduced, but it is doubtful if any useful purpose is served by giving fanciful names to duodenal deformities in view of the fugitive and essentially variable appearances of barium food in the duodenum. We must condone this fault, to which the authors are rather prone, in view of their careful study of the underlying pathological condition. The unpleasing method of writing descriptive lettering across blocks, which has been growing more common of late, has happily been avoided by the use of neat marginal explanatory diagrams.

The work is an important one, written as it is in close collaboration by a physician, a surgeon, and a radiologist, working at the same clinic with abundance of clinical material. It will appeal to all three branches in this country, if most strongly to the radiologist.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE. July and August.—Interesting facts are given in the July issue by C. O. Sappington when reporting on five years' sickness and accident experience in the Edison Electric Illuminating Co. of Boston. Common colds caused 34·3 per cent. of absenteeism, with a case-rate of 47 per 100 employees, and an average loss of 3·2 days per case. Among women dysmenorrhœa came second, with a rate of 32 per 100. For severity functional nervous diseases headed the list with an average loss of 9·4 days per case; rheumatism, arthritis, and gout came second, with an average loss of 7·4 days. Those affections which made up the bulk of the number of cases were lowest in severity rates, but their aggregate amount of lost time was greatest. A progressive decrease in rates was found as age increased—quite an unusual phenomenon. Women experienced more absenteeism than men. The average case cost was lowest for diseases of the stomach and highest for occupational accidents; home accidents had a high case cost, but only half that of occupational accidents. Sickness caused 20 times as many cases of absenteeism as accidents and seven times as much lost time. The plea put forward in THE LANCET (1921, i., 985) for closer study of the common cold is quoted and supported. —In contrast H. E. Elkind deals with mental hygiene in large mercantile establishments in Boston. Here functional nervous disease cost much more than rheumatism, arthritis, and gout taken together with the common cold. The results obtained by applying psychological tests are given; some positive association was found between native intelligence and clerical ability.—E. Ciampolini draws attention to carbon monoxide hazard in public garages. The blood of a number of men was examined and in 70 per cent. traces of CO were found; headache was common, and gastric symptoms were present in many. Atmospheric tests showed the presence of CO in 77·5 per cent. of garages inspected, amounting to 0·2 per cent. in one case and to 0·15 per cent. in nine. Ventilation was as a rule quite inadequate. Clearly carbon monoxide is a definite risk in garages. ——The issue for August is devoted entirely to experimental studies in lead absorption. A. S. Minot finds that after giving lead acetate to cats by mouth it is absorbed into the circulation only in small amounts; the liver protects the rest of the organism, and most of the lead is excreted in the bile; a small amount reaches the various tissues; bones show a special affinity for lead, and retain it when the other tissues may be clear; in bones lead is a harmless deposit; lead does harm during transport rather than during storage. In a second paper the same author points out that lead compounds when insufflated escape the protective action of the liver and so are rapidly distributed through the organism. Given subcutaneously absorption is so slow as to be of little practical importance.—A. S. Minot and J. C. Aub give the result of analyses of the various tissues of seven patients with known histories of exposure to lead. The findings resemble those found in experimental animals. While symptoms are present lead is distributed generally. After exposure has ceased there is selective localisation in temporarily harmless skeletal deposit.—L. T. Fairhall and C. P. Shaw report on a research into the deposition of lead salts in bone. Lead is quantitatively removed from solution in a short time by crushed bone, where it appears to replace calcium and to exist as a phosphate. The hypothesis is that lead is deposited by a process of adsorption of colloidal lead salts.

almost any operation which he may be called upon to perform. This is an attractive feature. One of the best sections is that which treats of the thorax. Curiously, in an almost encyclopædic work of this description there is no account of Lilienthal's successful case of resection of the thoracic œsophagus, nor of Torek's classical case. On p. 661 there is a small inaccuracy. Jonnesco's operation upon the sympathetic for exophthalmic goitre includes the removal of the inferior cervical and the first thoracic ganglia. It is rather important to emphasise this, since it has been demonstrated that the nerves which influence the activity of the thyroid come almost solely from the inferior ganglion. In a long book it is safe to say that no points stand out for serious adverse criticism. The high level attained in the previous volumes has been maintained.

DISEASES OF WOMEN.

Third edition. By Ten Teachers. Under the direction of COMYNS BERKELEY, M.D., M.C. Camb., F.R.C.P. Lond., Obstetric and Gynæcological Surgeon to Middlesex Hospital. London: Edward Arnold and Co. 1924. Pp. 641. 24*s*.

THE appearance of a third edition of this text-book within five years of its first publication is an index of the esteem in which it is held. It has filled adequately the need for a concise and handy volume dealing with the pelvic ailments of women. In 600 odd pages the book provides a clear exposition of the views of ten well-known London teachers of gynæcology welded into one composite whole under the editorship of Drs. Comyns Berkeley, Russell Andrews, and J. S. Fairbairn. The present edition follows in general lines its predecessors, and minor alterations only are noticeable. For example, the section on adenomyoma is brought up to date, and we notice for the first time the introduction in a student's text-book of the new term Endometrioma in relation with extra-uterine neoplasms of this character. The book does not profess to be exhaustive, but it is ample for the student's requirements. The practitioner also will find much sound information in its pages. A section likely to be particularly useful to the man in practice is that dealing with chronic ill-health in women from the psychological aspect. Neurasthenia in relation to pelvic disorders is only too common, and the chapter which discusses this problem is admirable.

We note that the sections on urinary disorders and intestinal disorders are still retained. In a text-book devoted primarily to the diseases of women it would appear hardly necessary to discuss at length the course of acute and chronic appendicitis—conditions which are so thoroughly considered in works on general surgery. And the completeness with which such rare conditions as inversion of the uterus are treated seems out of place in a text-book of this type. The same may be said of rhabdomyosarcoma of the uterus, interstitial pregnancy, and the technical details of such operations as trachelorrhaphy and amputation of the vulva. The man who reads this book will not perform these operations. If he does he will require more experience than can be gained from woodcuts, however excellent. The student without experience is unable to distinguish between the common and the rare, and too often lays undue emphasis upon impressions gained from text-book illustrations.

The book will continue to occupy its deservedly high place amongst the gynæcological text-books of to-day. Its popularity should be enhanced owing to the reduction in price.

MATTER AND CHANGE.

An Introduction to Physical and Chemical Science. By WILLIAM CECIL DAMPIER WHETHAM, M.A., F.R.S., Fellow and sometime Senior Tutor of Trinity College, Cambridge. Cambridge: At the University Press. 1924. Pp. 280. 7*s*. 6*d*.

THIS book, which is written for the general reader and for those whose main intellectual interests lie in other fields of thought, fulfils its purpose excellently. Few modern activities are possible without some knowledge of the basal sciences of chemistry and physics, but progress in these is so rapid that a very few years abstinence from their study renders the outsider hopelessly out of date. The ordinary text-books of chemistry and physics are laden with detail, and it is a labour to read them save for the direct and numerous purposes which they serve, but in Mr. Whetham's book detail is subordinated to essentials and general principles. The author discusses the main branches of his subjects clearly and philosophically. He has ruthlessly discarded a great deal of material which goes to make up the bulk of the ordinary text-book, and in consequence the general reader is not distracted from the appreciation of the important, fundamental principles. Of their charity, mathematicians and physicists are apt to flatter their readers, and it may be doubted whether the more biologically minded individual will agree that Mr. Whetham employs only "the simplest schoolroom mathematics." But even if some of the equations at first sight look rather terrifying, the author has really been lenient, and we can thoroughly recommend his book to the medical man who desires, not only to keep abreast of other sciences than his own, but also to appreciate the direction of modern medical research.

VENEREAL DISEASE.

Lectures on Gonorrhœa in Women and Children. By J. JOHNSTON ABRAHAM, M.D. Dub., F.R.C.S. Eng.; Surgeon, London Lock Hospitals; Senior Surgeon, Kensington General Hospital. London: William Heinemann, Ltd. 1924. Pp. 142. 7*s*. 6*d*.

THIS book, in the form of nine lectures, gives as brief a description as possible of the usual manifestations, immediate and remote, of gonorrhœa in women and children in order to dwell more particularly on the treatment of the various conditions. The arrangement of the matter is admirable and the author has succeeded wonderfully well in bringing before the practitioner the methods of treatment in a concise and definite form. As is natural in so small a book, certain instructions are laid down dogmatically, which in a larger work would be matter for discussion, but the lines of treatment set forth are sound.

The book is needed in this country and in our colonies. While much literature has accumulated in recent years on the subject of gonorrhœa in the male, little has been written of the disease in the female, and the information here given, unfortunately not well illustrated, will aid the practitioner materially in his treatment of the disease.

The methods of examination set down are sufficiently exact and the same is true of the tests for cure. Practitioners will find this is a valuable little book.

Recent Methods in the Diagnosis and Treatment of Syphilis. Second edition. By CARL H. BROWNING, M.D., D.P.H., and IVY MACKENZIE, M.A., B.Sc., M.D. Part I.: Diagnosis. Revised by CARL H. BROWNING, with chapters by JOHN CRUICKSHANK and T. TANIGUCHI. Part II.: Treatment. Revised by IVY MACKENZIE. With an introduction by ROBERT MUIR, M.D., F.R.S., Professor of Pathology in the University of Glasgow. London: Constable and Company, Ltd. 1924. Pp. 537. 42*s*.

THE first edition of this work appeared in 1911, when the modern lore of syphilis was in its infancy. Since then the literature on the subject has reached enormous proportions. On that account, and with wisdom, the subject-matter has been divided into two parts: I., "Diagnosis," for the rewriting of which Prof. Browning is responsible, and II., "Treatment," which Dr. Mackenzie has undertaken. The matter in the volume is original and has previously appeared in scientific journals; it is practically new, and is

THE UNIVERSITY OF LONDON PARLIAMENTARY ELECTION.

THE untimely and regretted death of Sir SYDNEY RUSSELL-WELLS has brought about unexpectedly, and at an interesting period in the history of the University of London, a Parliamentary election, and already there are three candidates in the field whose claims in respect of the University can be gauged by their public utterances and records, although so far all the formal election addresses have not been issued. The three candidates, each of whom may be said to place the interests of higher education above party considerations, are Sir JOHN ROSE BRADFORD, officially a Conservative, Dr. E. GRAHAM LITTLE, an Independent candidate, and Prof. A. F. POLLARD, officially a Liberal; and two points present themselves for decision to the minds of the electors. The first is, whether they will allow party considerations to decide their vote; and the second is, whether subordinating party considerations to the promotion of educational interests—a position which every University elector has a right to take up—they approve or disapprove of the reconstruction of the University of London, as foreshadowed in the recommendations of the Haldane Report. For here those who invite their suffrages are at variance. The intention of the Board of Education to set up a Departmental Committee to consider this Report is the reason given by Dr. LITTLE for his candidature, the assumption being that his opponents will not be adverse to such a Committee being set up, and that its formation implies a new constitution for the University on the lines of the Report. Dr. LITTLE is in entire opposition to the Report, while the other candidates, without endorsing all its recommendations, see the necessity for certain changes which it advocates. The wording of the reference to the Departmental Committee has not been studied by some of the partisans who have made public utterances. It is as follows: "To consider the Final Report of the Royal Commission on University Education in London dated the 27th March, 1913, and, having regard to present circumstances and after consultation with the persons and bodies concerned, to indicate what are the principal changes now most needed in the existing constitution of the University of London and on what basis a Statutory Commission should be set up to frame new Statutes for the University." The action of the Board of Education in setting up the Departmental Committee has been challenged on a hazy understanding of the programme which will lie before that body, it being taken for granted that to consider the Final Report would be to bless it and put it into force.

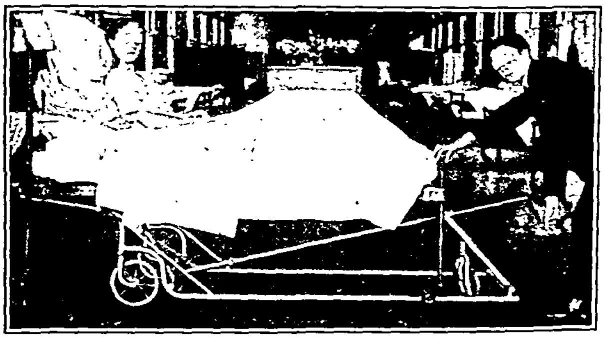
Of the three candidates it is extremely pleasant to be able to say that they are personally unexceptionable. They can express diverse views on the honest and strong foundation of an intimate knowledge of what they are talking about. Each believes that he represents the right, and this should ensure for the contest close attention from all those of our readers who are interested in higher education, whether electors or not, for fundamental matters in professional training will be on the carpet. Those who believe that the recommendations of the Haldane Report, if carried into effect, would damage the University irretrievably by creating a bureaucratic Senate, and by exalting the teaching colleges at the expense of the external students, will give their votes to the candidate who sees no good in a further inquiry into the constitution of the University. But the new Committee may not, in the altered recommendations that they are certain to make, take the course which has been anticipated by those definitely opposed to the Haldane Report—surmises even when supported by plausible arguments remain surmises. Dr. LITTLE, explaining his candidature as due to the revival by the Government of the recommendations of the Haldane Report, comes forward on the invitation of the University of London Graduates' Association, which is a non-political body, but makes a first-class point for a Conservative platform in suggesting that, as the present state of the University calls for no drastic alterations, there is no need for doing anything. Sir JOHN ROSE BRADFORD is opposed to a Statutory Commission carrying out the recommendations of the Haldane Report, and has modified a previously expressed view as to the abolition of external medical degrees. Prof. POLLARD, forecasting the results of the new Departmental Committee, has stated that he is not in favour of abolishing degrees, granted only on examinational tests, until their place can be taken by something which the student needs and desires more. He comes to the heart of the situation as it affects the medical profession in particular. The constitution of a smaller Senate, or the development of one of the internal colleges to be a centre around which the University revolves, would create situations which are more remote to the interests of the external student than the curtailment or abolition of the right to obtain degrees by examination, without affiliation to a teaching body. This has been the great privilege of the University of London. Its function as an Imperial examining board has been its pride throughout the existence of the University, and it can easily be understood that any attempt to tamper with the privilege arouses stalwart opposition. Yet that privilege was a gift to meet a time, not to satisfy perpetual requirements. Undoubtedly great men and successful men, and some who have been both great and successful, have owed their positions to the extraordinary facilities offered by the University of London for independent and private study, but if those opportunities, which have worked so well in the past, can be replaced by opportunities as wide and as wise, but more in touch with the present, there can be nothing sacrilegious in interference, though justice and prudence would suggest that the interference should be made with all possible respect for existing rights.

General pictures have a way of not being accurate, owing to a necessary absence of detail, and the situation cannot be summed up by saying that we have here a contest between those who think that the function of the University is to train learned men and those who think that the function of the University is to train useful citizens; and yet some such parting of the ways is held by the supporters of the various candidates to be in contemplation. Of course, the function of a university is to do both things, and that is what makes the medical graduate so typical a figure, his academic ideals and his social utility being limited only by the progress of science. Now medicine differs from other callings in the absolute necessity which its pursuit entails upon the student that she or he should receive instruction in an approved school in order to meet examinations whose standard is

New Inventions.

A BED-LIFTING TROLLEY.

To transfer a patient on a trolley from his bed to the operating theatre and back again necessitates several liftings, at least four: (1) If a preliminary injection of morphine has been given, this disturbs the patient and interferes with the action of the drug; (2) if the patient is in pain the lifting may cause a great deal of suffering and even shock; (3) if the operating theatre is at some distance from the ward the patient is liable to suffer from exposure to cold during his journey. I am persuaded that this exposure is a potent factor in the causation of post-operative lung affections. To minimise these disadvantages the patient is often brought to the theatre in his bed, but unless the bed is provided with large wheels, the procedure is not always a simple one. I have therefore designed an appliance which has been tested for several months. The principle of the mechanism is that of an oblong box from which the top and bottom have been removed and the sides fastened together by hinges. It is obvious that by pressing together two opposite edges the whole will collapse. Imagine, passing diagonally across the box, a rod provided with a screw and so mounted that when it is turned in one direction the box will collapse, and when it is turned in the other, the box will resume its rectangular shape. The actual apparatus is shown in the illustration. It consists of an undercarriage provided with three movable wheels, so arranged that the apparatus can be turned in its own length. At either end of this are hinged the supports of a stretcher top (which can be made a separate piece if one wishes). This is raised and lowered, by a diagonal screw, acting in exactly the same way as in the case of the box. When the screw is turned one way the stretcher is lowered so that it can be slipped under the patient's bed; when the handle is turned in the opposite direction the stretcher is raised, carrying the bed with it. Patient, bed, and trolley can now be easily wheeled to the operating theatre; and, after the anæsthetic has been administered on the bed, the patient can be brought to the side of the table and lifted on to it. If the head of the bed gets in the way of the anæsthetist before the morphia is given the mattress can be readily turned round head to foot. During the operation the bed can be warmed and after the operation the patient is lifted back from the table to his bed. Not only are two liftings definitely eliminated, but the remaining two, being carried out in the theatre, where there are usually many hands to help, are done more gently, and there is no risk of the patient being "bumped" back into bed. With this apparatus it is possible to bring a bed to the casualty receiving room for cases of severe injury or internal hæmorrhage; and in the case of chronic cases it can be used to wheel a patient in his bed about his house or grounds. It can, of course, be used as an ordinary theatre trolley. The apparatus is the result of a good deal of experiment, and I should like to thank Messrs. Arnold and Sons, of Wigmore-street, for their skilful coöperation and assistance. It is made of steel tubing and is extremely strong and at the same time light.



ARTHUR EDMUNDS, C.B., M.S., F.R.C.S.,
Surgeon to King's College Hospital.

Reports and Analytical Records.

AMBRIODIN CENTAUR.

(THE CENTAUR CHEMICAL CO., LTD., BASSISHAW HOUSE, BASINGHALL-STREET, LONDON, E.C. 2.)

SOME years ago we published the composition of this compound as ammonium bromide 5 gr., potassium iodide 1 gr. combined with a laxative, and these are the ingredients given in the analysis published by the Centaur Chemical Company. The formula is therefore well known to medical men as of use when bromide is indicated, and the tablets offer a convenience in administration. Advantages are claimed in the treatment of epilepsy by this combination as opposed to the exclusive use of potassium bromide, and clinical evidence is forthcoming in support of the claim. Each tablet contains ammonium bromide 0·324 g., potassium iodide 0·0648 g. with suitable laxatives and tonics, and from two to six tablets are recommended to be taken twice daily, the dosage and time of administration obviously to be under the direction of the physician. Medical men have also found the preparation of use in general depression, irritability, and the conditions rather loosely included under the term of neurasthenia. Here the recommended dose is smaller, and the employment of the remedy must be watched and the dosage varied according to the effects produced. The tablets are supplied sugar-coated or uncoated, the latter undergoing ready solution in the stomach.

PREPARED FOODS.

(MESSRS. GEORGE KING AND CO.'S FOODS, ALBION FOOD MILLS, SYCAMORE-STREET, LONDON, E.C.1.)

Three foods manufactured by this firm have been submitted to us for examination: (1) Wheaten food; (2) prepared patent cooked oatmeal (Scotch), medium grind; (3) prepared patent cooked oatmeal (Scotch), fine grind. When analysed these were found to have the composition :—

—	Wheaten food, per cent.	Oatmeal, medium grind per cent.	Oatmeal, fine grind, per cent.
Moisture	4·0	3·3	3·8
Mineral matter ..	0·6	2·0	1·9
Fats	1·4	10·5	10·0
Protein	12·3	11·2	12·6
Carbohydrates and cellulosic matter	81·7	73·0	71·7
Matter soluble in cold water ..	10·8	4·8	6·0
Calorie value, per lb.	1807	2010	1989

The wheaten food is ordinary flour of a good grade which has been cooked or heated sufficiently to destroy its gluten-forming capacity, and incorporated with it is a small amount of a finely ground malted cereal. Evidence of this is afforded by the presence of a starch-liquefying diastase. According, however, to the instructions provided for preparing the food, the malt can play no part in converting the starch of the wheaten flour into soluble sugars. Many practitioners, therefore, would deprecate this food being given at so early an age as 5 months.

Oatmeal (medium and fine grind): These are de-husked oatmeals of a high grade which have been submitted to a preliminary cooking process in order to save time in preparing them for the table. The analytical figures are those usually found for good Scotch oatmeals. It will be noted that the percentage of fat is much higher than in the wheaten food. This is characteristic, and is one of the principal reasons why oatmeal is so valuable a food material.

Those who believe that the recommendations of the Haldane Report, if carried into effect, would damage the University irretrievably by creating a bureaucratic Senate, and by exalting the teaching colleges at the expense of the external students, will give their votes to the candidate who sees no good in a further inquiry into the constitution of the University. But the new Committee may not, in the altered recommendations that they are certain to make, take the course which has been anticipated by those definitely opposed to the Haldane Report—surmises even when supported by plausible arguments remain surmises. Dr. Little, explaining his candidature as due to the revival by the Government of the recommendations of the Haldane Report, comes forward on the invitation of the University of London Graduates' Association, which is a non-political body, but makes a first-class point for a Conservative platform in suggesting that, as the present state of the University calls for no drastic alterations, there is no need for doing anything. Sir John Rose Bradford is opposed to a Statutory Commission carrying out the recommendations of the Haldane Report, and has modified a previously expressed view as to the abolition of external medical degrees. Prof. Pollard, forecasting the results of the new Departmental Committee, has stated that he is not in favour of abolishing degrees, granted only on examinational tests, until their place can be taken by something which the student needs and desires more. He comes to the heart of the situation as it affects the medical profession in particular. The constitution of a smaller Senate, or the development of one of the internal colleges to be a centre around which the University revolves, would create situations which are more remote to the interests of the external student than the curtailment or abolition of the right to obtain degrees by examination, without affiliation to a teaching body. This has been the great privilege of the University of London. Its function as an Imperial examining board has been its pride throughout the existence of the University, and it can easily be understood that any attempt to tamper with the privilege arouses stalwart opposition. Yet that privilege was a gift to meet a time, not to satisfy perpetual requirements. Undoubtedly great men and successful men, and some who have been both great and successful, have owed their positions to the extraordinary facilities offered by the University of London for independent and private study, but if those opportunities, which have worked so well in the past, can be replaced by opportunities as wide and as wise, but more in touch with the present, there can be nothing sacrilegious in interference, though justice and prudence would suggest that the interference should be made with all possible respect for existing rights.

General pictures have a way of not being accurate, owing to a necessary absence of detail, and the situation cannot be summed up by saying that we have here a contest between those who think that the function of the University is to train learned men and those who think that the function of the University is to train useful citizens; and yet some such parting of the ways is held by the supporters of the various candidates to be in contemplation. Of course, the function of a university is to do both things, and that is what makes the medical graduate so typical a figure, his academic ideals and his social utility being limited only by the progress of science. Now medicine differs from other callings in the absolute necessity which its pursuit entails upon the student that she or he should receive instruction in an approved school in order to meet examinations whose standard is

New Inventions.

A BED-LIFTING TROLLEY.

To transfer a patient on a trolley from his bed to the operating theatre and back again necessitates several liftings, at least four: (1) If a preliminary injection of morphine has been given, this disturbs the patient and interferes with the action of the drug; (2) if the patient is in pain the lifting may cause a great deal of suffering and even shock; (3) if the operating theatre is at some distance from the ward the patient is liable to suffer from exposure to cold during his journey. I am persuaded that this exposure is a potent factor in the causation of post-operative lung affections. To minimise these disadvantages the patient is often brought to the theatre in his bed, but unless the bed is provided with large wheels, the procedure is not always a simple one. I have therefore designed an appliance which has been tested for several months. The principle of the mechanism is that of an oblong box from which the top and bottom have been removed and the sides fastened together by hinges. It is obvious that by pressing together two opposite edges the whole will collapse. Imagine, passing diagonally across the box, a rod provided with a screw and so mounted that when it is turned in one direction the box will collapse, and when it is turned in the other, the box will resume its rectangular shape. The actual apparatus is shown in the illustration. It consists of an undercarriage provided with three movable wheels, so arranged that the apparatus can be turned in its own length. At either end of this are hinged the supports of a stretcher top (which can be made a separate piece if one wishes). This is raised and lowered, by a diagonal screw, acting in exactly the same way as in the case of the box. When the screw is turned one way the stretcher is lowered so that it can be slipped under the patient's bed; when the handle is turned in the opposite direction the stretcher is raised, carrying the bed with it. Patient, bed, and trolley can now be easily wheeled to the operating theatre; and, after the anæsthetic has been administered on the bed, the patient can be brought to the side of the table and lifted on to it. If the head of the bed gets in the way of the anæsthetist before the morphia is given the mattress can be readily turned round head to foot. During the operation the bed can be warmed and after the operation the patient is lifted back from the table to his bed. Not only are two liftings definitely eliminated, but the remaining two, being carried out in the theatre, where there are usually many hands to help, are done more gently, and there is no risk of the patient being "bumped" back into bed. With this apparatus it is possible to bring a bed to the casualty receiving room for cases of severe injury or internal hæmorrhage; and in the case of chronic cases it can be used to wheel a patient in his bed about his house or grounds. It can, of course, be used as an ordinary theatre trolley. The apparatus is the result of a good deal of experiment, and I should like to thank Messrs. Arnold and Sons, of Wigmore-street, for their skilful coöperation and assistance. It is made of steel tubing and is extremely strong and at the same time light.

Reports and Analytical Records.

AMBRIODIN CENTAUR.

(THE CENTAUR CHEMICAL CO., LTD., BASSISHAW HOUSE, BASINGHALL-STREET, LONDON, E.C. 2.)

SOME years ago we published the composition of this compound as ammonium bromide 5 gr., potassium iodide 1 gr. combined with a laxative, and these are the ingredients given in the analysis published by the Centaur Chemical Company. The formula is therefore well known to medical men as of use when bromide is indicated, and the tablets offer a convenience in administration. Advantages are claimed in the treatment of epilepsy by this combination as opposed to the exclusive use of potassium bromide, and clinical evidence is forthcoming in support of the claim. Each tablet contains ammonium bromide 0·324 g., potassium iodide 0·0648 g. with suitable laxatives and tonics, and from two to six tablets are recommended to be taken twice daily, the dosage and time of administration obviously to be under the direction of the physician. Medical men have also found the preparation of use in general depression, irritability, and the conditions rather loosely included under the term of neurasthenia. Here the recommended dose is smaller, and the employment of the remedy must be watched and the dosage varied according to the effects produced. The tablets are supplied sugar-coated or uncoated, the latter undergoing ready solution in the stomach.

PREPARED FOODS.

(MESSRS. GEORGE KING AND CO.'S FOODS, ALBION FOOD MILLS, SYCAMORE-STREET, LONDON, E.C.1.)

Three foods manufactured by this firm have been submitted to us for examination: (1) Wheaten food; (2) prepared patent cooked oatmeal (Scotch), medium grind; (3) prepared patent cooked oatmeal (Scotch), fine grind. When analysed these were found to have the composition:—

—	Wheaten food, per cent.	Oatmeal, medium grind per cent.	Oatmeal, fine grind, per cent.
Moisture	4·0	3·3	3·8
Mineral matter ..	0·6	2·0	1·9
Fats	1·4	10·5	10·0
Protein	12·3	11·2	12·6
Carbohydrates and cellulosic matter	81·7	73·0	71·7
Matter soluble in cold water ..	10·8	4·8	6·0
Caloric value, per lb.	1807	2010	1959

The wheaten food is ordinary flour of a good grade which has been cooked or heated sufficiently to destroy its gluten-forming capacity, and incorporated with it is a small amount of a finely ground malted cereal. Evidence of this is afforded by the presence of a starch-liquefying diastase. According, however, to the instructions provided for preparing the food, the malt can play no part in converting the starch of the wheaten flour into soluble sugars. Many practitioners, therefore, would deprecate this food being given at so early an age as 5 months.

Oatmeal (medium and fine grind): These are de-husked oatmeals of a high grade which have been submitted to a preliminary cooking process in order to save time in preparing them for the table. The analytical figures are those usually found for good Scotch oatmeals. It will be noted that the percentage of fat is much higher than in the wheaten food. This is characteristic, and is one of the principal reasons why oatmeal is so valuable a food material.

almost complete arrest of hostilities is a matter of common knowledge. Within six months of that period the ordinary business of life was in many parts of the world temporarily brought to a standstill by the ravages of the disease; in North America the coffin-makers were unable to cope with the demands for their wares; whilst in tropical Africa, Asia, and the Oceanic Islands natives in unknown thousands crawled into the forests to die.

To-day little more is known concerning the agency responsible for these dramatic occurrences than was available at the moment when the document on "three-day fever" was originally drafted. Rival bacteriologists may sometimes indulge in learned disputes on the subject, but no man can say with absolute authority whether certain diseases, such as encephalitis lethargica, are entirely unrelated to influenza. Without suggesting that it is in any way probable, we can say that it is a possibility that minor epidemics such as that recorded in the article in our columns to-day bear some relation to pandemic influenza. The possibility gives an important incentive to efforts to discover their true pathology.

◆

A STATISTICAL REVIEW OF 1923.

THE Registrar-General has issued, in the third week of August, his medical tables [1] for the previous year, and, alongside the statistical "records" which this review contains, should be gratefully noted the timeliness of its appearance. For the tables are of great importance to executive health officers as the basis for their local reports, while last year the review was given out in November, in the previous year not at all. The edge of the interest has been tken off these truly wonderful vital statistics by the forecast issued in January,[2] when the Registrar-General remarked that the birth-rate for England and Wales as a whole was (apart from the war years) the lowest recorded, while the death-rate and infantile mortality were actually the lowest on record. His provisional figures have undergone no substantial modification, the corrected birth-rate for 1923 being 19·7, the death-rate 11·6, and the infant mortality-rate 69. From the figures now given it appears that the actual number of births was 758,131 (or 21,993 fewer than in 1922), the actual number of deaths 444,365 (or 41,864 fewer than in 1922), leaving a plus balance of 313,766, equivalent to a rate of 8·1 per 1000 living, denoting the natural increase of population. This increase shows a higher rate (the Registrar-General calls it an "improvement") than in 1922, when the rate was 7·6 per 1000. The deaths in 1923 were, in fact, little more numerous than in 1862, when the population was hardly over 20,000,000 and the death-rate was 21·4; now it has fallen below 12 per 1000 for the first time. The infant mortality-rate of 69 is a measure of deaths under 1 year of age amounting to 52,582, an appalling enough figure when stated in this form. The mortality of children of school age has also reached its lowest record. In regard to infectious diseases, the death-rates from enteric fever, diphtheria, and phthisis are the lowest on record, as also (with one exception) is that from scarlet fever. Influenza shows the lowest mortality since 1917 and whooping-cough since 1919. Cancer, in the unvarnished words of the report, "shows the highest rate yet received"; the total figures, and those which we have given week by week in our summaries of health officers' reports, denote a vast amount of unrelieved misery which weighs heavily upon medical science. We hope it will not be long before we receive Dr. Stevenson's illuminating commentary upon this compendium, which should in the meantime be studied in the light of Sir George Newman's cautionary tale issued by the Ministry of Health.

Annotations.

"Ne quid nimis."

A GREAT MUNICIPAL HEALTH OFFICER.

DR. E. W. Hope's impending retirement from the position of medical officer to the City and Port of Liverpool severs a very intimate connexion. His tenure of office has been synchronous with the great activity in public health matters which has been in progress since the passing of the Public Health Act of 1875. Liverpool was a pioneer in municipal hygiene. The first medical officer of health in England, Dr. W. H. Duncan, was appointed there in 1842. His successor, Dr. W. S. Trench, was followed in turn by Dr. Stopford Taylor, to whom, in 1883, Dr. Edward W. Hope was appointed assistant. In 1887 Dr. Hope became medical superintendent of Park Hill Fever Hospital, and in 1894, on the retirement of Dr. Taylor, he was appointed medical officer of health of the city.

From early days Dr. Hope was associated with the University movement; in 1886 he became lecturer on public health to University College, and subsequently was appointed professor of public health, first at the College when it was affiliated to the Victoria University, and latterly at the University of Liverpool, when it obtained its charter in 1903. Dr. Hope has frequently pointed out that the unenviable notoriety for disease and mortality which characterised Liverpool at the time of his appointment was due in large measure to the rapid growth of the city at a time when public health requirements were disregarded, and in the second place to its peculiar vulnerability to the attacks of imported disease. In 1883 the city had no hospital for infectious diseases, and there was practically no port sanitary administration to check the importation of exotic disease. The great needs of Liverpool necessitated a forward policy, and under the wise guidance of Dr. Hope the city council repeatedly obtained special legislative powers, while utilising to the full the provisions of the public health measures applying to the whole country. When Dr. Hope took office the population of Liverpool was only 540,000; in 1921 it had increased to 817,000, but the total deaths in this larger population were less by nearly one quarter. During this period housing received much attention, for in 1883 there were 23,690 cellars occupied as human dwellings and sanitation was in other respects in a very backward state. In the late 'eighties Liverpool was one of the few places where typhus fever could still be studied. During Dr. Hope's connexion with the city there have been built up a system of hospitals for infectious disease, an efficient and elaborate port sanitary administration, and all the other essentials of a modern civic health department, including an up-to-date school medical service and maternity and child welfare department.

Throughout his work as municipal officer Dr. Hope never came into conflict with independent medical practice. The good feeling existing between him and his medical colleagues found expression in his election some years ago to the presidency of the Liverpool Medical Institution. A recent example of effective coöperation is afforded by the harmonious working of the city council with the Consular Corps, His Majesty's Customs, the Mersey Docks and Harbour Board, the shipowners, and the neighbouring Merseyside sanitary authorities. Dr. Hope himself is known to be in favour of a more complete unification of the medical public health services. In his retirement, where the warm wishes of all public health workers go with him, it is to be hoped that he will still assist us with [illegible]actical idealism.

not fixed independently by any university or corporation, but laid down by a representative body under Government ægis. Such conditions, it will be seen, are wholly at variance with the picture of the scholar who, failing any suitable environment or chances, wins his way to a degree; while that is the ideal, and a noble one, of external studentship at the University of London. No medical student can dispense with university or collegiate training, and to provide wider opportunities for graduation is the function of those excellent universities whose recent development in our provinces is tangible proof of the progress of education in the country. We cannot sympathise with any movement, through committees of inquiry or statutory commissions, which would prevent properly trained medical students from obtaining the coveted London degree; but it is not accurate to suggest that these students are the product of home study, or representative in any way of the class of external students of whom the University of London has been such an admirable protector. But the University has charges at home as well as abroad, and the London schools have felt that their students, through lack of intimate association with the University, have been placed at a professional disadvantage. The Haldane Report certainly designed to meet this position.

◆

THE TISSUE PATHOLOGIST.

DURING the war, in every branch of medicine, circumstances necessitated the employment as experts of men whose chief claims to such positions were their enthusiasm and devotion to duty. Even in the highly organised German medical service the existence of *ersatz* bacteriologists, surgeons, and so forth was openly recognised. And it must be admitted that, on the whole, the work was very well done. But with the return to normal conditions it was once more justly expected of the expert that he should have an expert's training. In the field of clinical pathology, however, a greater tolerance has been exercised, especially where tissue diagnosis is concerned. The impetus given to laboratory medicine in the last few years, as Dr. KENNETH M. LYNCH, of Dallas, Texas, has recently pointed out,[1] has produced a demand for clinical pathologists out of all proportion to the supply of people adequately prepared to undertake this work. Whereas the simpler laboratory procedures can be satisfactorily performed by the beginner after a comparatively short period of training and practice, the more difficult examinations demand a much more prolonged apprenticeship. Especially is this so in the branch of histological diagnosis which, in the view of Dr. LYNCH, is "the most difficult and exacting in the matters of knowledge, experience, and judgment of all the things that the laboratorian is called on to do." The question naturally arises as to what constitutes the necessary minimum of training for the pathological histologist before he can be considered fit to undertake this work.

In order to gather opinions on this point, Dr. LYNCH sent a questionnaire to a number of leading pathologists in all parts of America. The answers received were practically unanimous in demanding a much more stringent standard and a much more arduous training than might have been expected. The general consensus of opinion was that the candidate should be qualified from a reputable medical school, should have had some experience of hospital service, and should have served an apprenticeship from two to three years in a laboratory through which passes abundant material. While such a training may be considered adequate to equip a man for ordinary routine work a further period of from three to five years "under an able leader, in a service with abundant necropsy and surgical diagnostic material. with full opportunity to observe end-results, should qualify a man of personal fitness to do critical anatomic analysis of any and all diseased tissue." A probation of this magnitude may sound unnecessarily formidable to those whose work lies in other directions, but its reasonableness will appeal to the pathologist in proportion to his experience of histology. The reason why there are so few tissue pathologists of this calibre is not far to seek. The prizes in pathological histology are few and meagre; the best men are rarely attracted to it, and to those who are a large practice in routine diagnosis is uncongenial. It frequently happens, therefore, that tissue diagnosis falls into the hands of those who are ill-equipped to undertake it, with untoward results. The remedy rests with the medical profession, especially with the practitioners of surgery who are chiefly concerned. If first-class diagnosis is demanded, it will be forthcoming. The question is essentially an economic one.

◆

EPIDEMIC PLEURISY.

WE publish to-day a clinical note by Drs. W. ATTLEE, A. M. ANSLER, and D. C. BEAUMONT describing an epidemic which occurred in Eton College in the early summer of this year. Fully 50 patients. boys from 14 to 18 years of age, were affected, whilst sporadic cases of a similar nature were observed in the neighbourhood. The main features of the disease were sore-throat, sometimes in the form of a granular pharyngitis, and sometimes of a follicular tonsillitis, a pyrexia lasting a few days only but tending to relapse, and pleurodynia often associated with a marked pleural friction-sound. With each relapse there was a tendency for a fresh patch of pleurisy to appear, but cough and pneumonic symptoms were conspicuously absent. Convalescence was somewhat protracted, anæmia and debility not infrequently being sufficient to necessitate the granting of sick-leave. Cardiac, renal, or arthritic complications were never observed. A closely similar epidemic was noted in THE LANCET of July 12th of this year, when Dr. BRUCE WILLIAMSON reported an outbreak which had occurred at the country branch of the Paddington Green Children's Hospital. Differences between the clinical manifestations of these two epidemics were so slight that it is reasonable to conclude that the same causal agency was responsible for both, especially in view of the fact that the two institutions involved are situated within a mile of one another.

Descriptions of such epidemics are a perennial reminder of the obscurity which still envelops even the more important infectious diseases. An official paper, circulated to the medical officers of army units in the north of France in the summer of 1918, gave an account of an epidemic disease which had recently appeared and which the writers termed "three-day fever." It was said to be a condition of mild pyrexia of transient course, without complications or sequelæ. Its brief duration and the absence of grave consequences were said to make isolation and serious treatment alike unnecessary. Yet within a month of the circulation of this document the hospitals and graveyards were being choked with the results of this disease, which by then was recognised as pandemic influenza. We do not yet know to what extent this disease was responsible for checking the final desperate offensive of the German armies, but that in many sectors of the field of war it led to it should, as is evident by the legend on the plate itself, be Henry IV. of France. Another interesting point which Prof. Bloch deals with in a learned fashion is the question as to whether kings received any priestly or quasi-priestly quality at their sacring. The upholders of royalty said they did; the upholders of the Papal temporal powers, whom Prof. Bloch calls Gregorians, said they did not. In both England and France the extreme claims of the Papacy were disliked and set at naught as far as might be, witness in France the movement known as Gallicanism and numerous documents quoted by Prof. Bloch, and by Mr. Alison Phillips in a letter on Papal Authority in England, which appeared in the *Times* of July 26th, 1924, in which among other documents he quotes an Act, 10 Henry VII. fol. 18: *Rex est persona mixta cum sacerdote, quia tam ecclesiasticam quam temporalem habet jurisdictionem.* We have not the space to follow Prof. Bloch all through his very careful and richly documented study, his researches into the meaning and history of unction, and into the rivalries between the upholders of the French and English claims respectively to be the only royal houses capable of exercising the rite of healing. Even as late as 1584 Reginald Scott said in his "Discoverie of Witchcraft" concerning healing of the king's evil, "which hath been alwaies thought and to this day is supposed to be a miraculous and peculiar gift, and a speciall grace given to the kings and queens of England." A little further on he maintains in a passage quoted by Prof. Bloch that the cure is not due to any special grace residing in the king. It is interesting to see, however, that the popular taste also trusted to charms, one of which we notice Scott quotes (p. 197, Nicholson's ed., 1886), "Remedies to cure the King's or Queen's Evil is first to touch the place with the hand of one that died an untimely death—Otherwise; Let a virgin fasting laie her hand on the sore and saie: Apollo denieth that the heate of the plague can increase where a naked virgin quencheth it: and spet three time upon it."

---

[1] Journal of the American Medical Association, July 12th, 1924.

THE NEW YORK ACADEMY OF MEDICINE.

THE annual report for 1923 of the New York Academy of Medicine records the steps taken in connexion with the offer made by the Carnegie Corporation in 1922 to provide a million dollars for a new building, provided the Academy furnished the site. A site was purchased at the cost of $754,500, but when preliminary plans were studied in accordance with Academy needs, it was found that the building would cost a considerably larger sum than had been originally estimated by either the Board of Trustees or the Carnegie Corporation. Negotiations with the Carnegie Corporation were renewed with the result that the Corporation requested the Academy to make a new study of its needs and endeavour to have plans prepared for a building which would be considerably less expensive than the original plan, which was roughly estimated between $1,750,000 and $2,000,000. The Trustees decided to appoint a director able to give the necessary time to the plans for the present and future activities of the Academy. This situation was placed before the Trustees of the Rockefeller Foundation with the result that the Foundation help in paying the salary of the director and his necessary expenses. Dr. Linsly R. Williams was appointed director and began his work on Jan. 1st, 1924.

The scope of the Academy has grown steadily since it was founded in 1847, primarily for the purpose of providing a reading-room for its members. The reading-room gradually developed into a large library, and at the present time there is a membership of 1450 resident fellows, and some hundreds of non-resident fellows, associates, and honorary fellows. At present the Academy is housed in a five-story building at 17, West 43rd Street, and in this building maintains a library, which is the second largest medical library in America, consisting of 130,000 volumes and 20,000 pamphlets. It is open to the Fellows of the Academy and during the morning to the general public, and is used by 30,000 readers a year. The Fellows of the Academy hold two stated monthly meetings which are devoted to scientific purposes, and a dozen different sections meet on the various specialties in medicine once a month during the winter. There are also several special lectures held during the year. The Academy is also the meeting place of the County Medical Society and of dental societies and medical associations of various types. It also provides office quarters for the Medical Society of the State of New York and a number of physicians' aid associations. There are also special committees appointed—one on the library, one on education, and one on public health. The work of the committee on public health has recently received notice in our columns. The committee on education directs the work of two former societies—the Society for the Advancement of Clinical Study and the Society for the Advancement of Medical Education. This committee maintains a bureau of clinical information which announces daily the list of operations to be performed in the various hospitals of New York City, and also gives information as to the various post-graduate courses which are open to the post-graduate students in this city. This work, which has only recently been organised, seems likely to develop in a way more or less similar to the post-graduate education which is being carried on under the auspices of the Royal Society of Medicine in London.

CONGENITAL MEGACOLON.

IN THE LANCET of August 2nd we drew attention to a case of this disease communicated to the Medical Society of Hospitals of Paris, in which the distended loop was of enormous dimensions. A monograph of 243 pages has just been published by Dr. G. Tonnini,[1] professor of surgery at the hospital in Mondolfo, which, besides a very complete bibliography and report of a case under his own care, contains a tabular analysis of the 62 cases hitherto published by Italian observers such as Mya and Concetti, who strongly supported Hirschsprung's original conception of the congenital nature of the affection, contributing by their researches, especially in the field of histology, to complete the anatomical picture of megacolon and to explain the changes which are peculiar to this disease. If the much-discussed theory of Hirschsprung is at the present day recognised as true for a certain limited number of cases of dilatation of the large intestine, this is due in a large measure to the validity of the arguments brought forward by Italian authors. To prove this is the task Prof. Tonnini, with the coöperation of Profs. Simonini and Schiassi of the University of Modena, has set himself to perform. A reference to the 62 cases published in Italy shows that there was incontrovertible evidence of congenital origin in the sense expressed by Hirschsprung and Mya, from (*a*) previous history and clinical and anatomical data 22 cases, (*b*) history and clinical data 5 cases, (*c*) clinical and anatomical data 14 cases, and (*d*) from anatomical data alone 5 cases. Five cases seemed to support the contention of Marfan, Neter, and others as to the ætiological part played by unusual length, multiple folds of the iliac, sigmoid, and recto-colic kinks. In two cases only was there definite mechanical obstruction, while in nine it was found impossible to assign any causation. This little work may be said to contain all that has been written up to the present time concerning megacolon, and will well repay perusal.

DERMAL MYIASIS AND THE TUMBU-FLY IN SIERRA LEONE.

THE prevalence of myiasis from the Tumbu-fly in Sierra Leone is very considerable, causing much discomfort to man, suffering and even death to domestic animals. The Tumbu-fly, *Cordylobia*

THE TREATMENT OF GLAUCOMA.

GLAUCOMA has given rise to more controversy than almost any other subject in the range of ophthalmology. A new treatment is reported by our Berlin correspondent, who refers to a paper read by Dr. Carl Hamburger before the Berlin Medical Society, advocating the subconjunctival injection of suprarenin. The effect produced, he says, is an enlargement of the pupil and decrease of pressure, while the choroidea becomes anæmic through blocking of the small arteries. The amount injected at one time is ½ c.cm., and the dose has to be repeated as soon as the symptoms recur. By this method he claims to have treated several patients with success. A method of counteracting increased intra-ocular tension by diminishing the quantity of blood entering the eye runs counter to all that has hitherto been taught on the subject. The dilatation of the pupil in itself is a contra-indication, and to cause retinal anæmia would hardly seem to be the best way to combat a disease in which retinal function is gravely impaired. Moreover, any good effect of a drug like suprarenin is bound to be only temporary. The aim of all rational treatment has hitherto been not to prevent the entry of fluid into the eye, but to facilitate its exit. In the normal eye the main channel of exit is Schlemm's canal, to which access is given through the trabecular tissue that occupies the angle of the anterior chamber. When this is made shallow by pressure from behind, due to increased intra-ocular tension, access is difficult, and when the pupil is dilated the angle is made still smaller and the difficulty increased. Hence, the traditional treatment of glaucoma—non-operative by eserin, which contracts the pupil, and operative by iridectomy, which provides an artificial anterior chamber. Often, however, these measures are insufficient, and the modern operations—Elliot's, Lagrange's, Herbert's—aim at providing an alternative exit for the intra-ocular fluid through the sclera. If there is one lesson which modern experience with regard to the treatment of glaucoma has taught, it is the danger of temporising too long. We should therefore hesitate to encourage the trial of any new experimental treatment without convincing reasons in its favour.

UNCENSORED SUGGESTIONS.

IN a scientific service with good discipline there is always the risk that improvements suggested by junior officers will not become known. The administrative officers, the seniors, arrange the work which is carried out by the executive officers, the juniors, whose daily work it is that will be most affected by the new procedures. But it is conceivably possible that even junior officers may have a few useful ideas even if not all of the highest value ("We are none of us infallible, not even the youngest of us"), which at any rate the seniors ought for their own sakes to hear about. We observe that the Medical Corps of the U.S. Navy, in its *Bulletin*, provides just such an outlet for its junior officers by publishing monthly suggestions from them, without any official comment whatsoever. Thus the service becomes aware of the ideas that are working within it long before these have secured official approval. Some day, and no one can tell when, some very valuable thought may emerge. Perkin, we are told, made his first aniline dye at the age of 18, and Pasteur, when he was 20, recognised that there were two kinds of tartaric acid crystals. In a recent (May) number of the *Bulletin* a junior medical officer, anxious to prevent the spread of infectious diseases in ships, states as his opinion that the most effective method would be to search out all cases where infectious disease might be incubating, before definite diagnosis is possible, rather than to carry out a scrupulous and minute disinfection of messes and bedding after the disease has become manifest, and has probably infected others. He calls this subsequent disinfection "bunkum," an expression which seems to suggest disapproval, and he adds that his captains are "astounded" when they find that terminal disinfection is not to be practised in their ships. Nothing will prove the correctness of this particular suggestion better than a statistical investigation, the result of which we hope to find in the *Bulletin* hereafter, for the question is of importance.

THE HEALING POWER OF KINGS.

A WORK of extraordinary erudition and one which has evidently entailed upon its author a vast amount of research has recently been published[1] by Prof. Marc Bloch. As in the case of so many ancient religious customs, the inquiry into the particular subject in hand involves an investigation into many ancillary customs, in this instance the divine right of kings: the quasi-sacerdotal privileges conferred upon sovereigns at their sacring by the holy oil with which they are anointed and by the priestly vestments with which they are clothed; various folk-lore beliefs, such as the curious gifts with which "seventh sons" are dowered and many others. All these matters Prof. Bloch has treated at length, and the result is a volume of great interest. His main theme was handled some years ago in a book entitled "The King's Evil,"[2] by Dr. R. Payne Crawfurd, to whom Prof. Bloch expresses his obligations more than once. We might compare the relation of the two books to the commentary of Servius upon Virgil, for Prof. Bloch may be said to comment upon and illustrate the facts and researches of Dr. Crawfurd in a way which, without at all minimising that admirable work, yet throws an additional flood of light upon a difficult subject, in much the same way as the commentary of Servius lights up, to take one instance, the sixth book of the Aeneid. Prof. Bloch begins by telling a delightful story. In 1340 Brother Francis, a Dominican, Bishop of Bisaccia, chaplain of King Robert of Anjou and for the moment ambassador of Edward III. of England, paid a diplomatic visit to the Doge of Venice with a view to negotiating an alliance, for the struggle known in after years as "the hundred years war" had just begun, although diplomatic efforts had not ceased. The ambassador pointed out that "the most serene Prince Edward, desirous of avoiding a slaughter of innocent Christians, had written to Philip of Valois, who calls himself King of France, proposing that he (Edward) and the French king should decide the point at issue without going to war, by a personal duel, by a combat between six to eight champions representing either side, or by one of the two following trials. If the King of France were as he said the true king, let him expose himself to some hungry lions, for lions it is known will never hurt a real king, or else that he should show himself a real king by healing the sick, which it is well known real kings can always do." But, adds the Bishop, "Philip in his pride rejected these proposals." Such is the text upon which Prof. Bloch founds his learned essay. He discusses at great length the origin of the healing touch in France and repudiates the tradition that it originated with Clovis; he considers that Robert the Pious, the second king of the House of Capet, was the first to exercise the healing powers for other diseases as well as for scrofula. By the time of Philip I., his grandson, the healing was limited to scrofula alone. In the same way as regards England, he considers that the healing of scrofula began with Henry II. or possibly with Henry I., but that neither Edward the Confessor nor any other Anglo-Saxon king pretended to any healing powers as king. Edward, it is true, is traditionally reported to have healed the sick, but as a saint, not in virtue of his kingship. Incidentally, the plate opposite p. 344 is wrongly described as Charles II. touching for the evil:

---

[1] Les Rois Thaumaturges: Etude sur le caractère surnaturel attribué à la puissance royale particulièrement en France et en Angleterre. Par Marc Bloch, Professeur à l'Université de Strasbourg. Great Britain: Humphrey Milford, Oxford University Press; Strasbourg et Paris: Librairie Istra. 1924. Pp. 542. Fr.30—12*s.* 6*d.*

[2] THE LANCET, 1911, ii., 1012.

it should, as is evident by the legend on the plate itself, be Henry IV. of France. Another interesting point which Prof. Bloch deals with in a learned fashion is the question as to whether kings received any priestly or quasi-priestly quality at their sacring. The upholders of royalty said they did; the upholders of the Papal temporal powers, whom Prof. Bloch calls Gregorians, said they did not. In both England and France the extreme claims of the Papacy were disliked and set at naught as far as might be, witness in France the movement known as Gallicanism and numerous documents quoted by Prof. Bloch, and by Mr. Alison Phillips in a letter on Papal Authority in England, which appeared in the *Times* of July 26th, 1924, in which among other documents he quotes an Act, 10 Henry VII. fol. 18: *Rex est persona mixta cum sacerdote, quia tam ecclesiasticam quam temporalem habet jurisdictionem.* We have not the space to follow Prof. Bloch all through his very careful and richly documented study, his researches into the meaning and history of unction, and into the rivalries between the upholders of the French and English claims respectively to be the only royal houses capable of exercising the rite of healing. Even as late as 1584 Reginald Scott said in his "Discoverie of Witchcraft" concerning healing of the king's evil, "which hath been alwaies thought and to this day is supposed to be a miraculous and peculiar gift, and a speciall grace given to the kings and queens of England." A little further on he maintains in a passage quoted by Prof. Bloch that the cure is not due to any special grace residing in the king. It is interesting to see, however, that the popular taste also trusted to charms, one of which we notice Scott quotes (p. 197, Nicholson's ed., 1886), "Remedies to cure the King's or Queen's Evil is first to touch the place with the hand of one that died an untimely death—Otherwise; Let a virgin fasting laie her hand on the sore and saie; Apollo denieth that the heate of the plague can increase where a naked virgin quencheth it: and spet three time upon it."

THE NEW YORK ACADEMY OF MEDICINE.

THE annual report for 1923 of the New York Academy of Medicine records the steps taken in connexion with the offer made by the Carnegie Corporation in 1922 to provide a million dollars for a new building, provided the Academy furnished the site. A site was purchased at the cost of $754,500, but when preliminary plans were studied in accordance with Academy needs, it was found that the building would cost a considerably larger sum than had been originally estimated by either the Board of Trustees or the Carnegie Corporation. Negotiations with the Carnegie Corporation were renewed with the result that the Corporation requested the Academy to make a new study of its needs and endeavour to have plans prepared for a building which would be considerably less expensive than the original plan, which was roughly estimated between $1,750,000 and $2,000,000. The Trustees decided to appoint a director able to give the necessary time to the plans for the present and future activities of the Academy. This situation was placed before the Trustees of the Rockefeller Foundation with the result that the Foundation help in paying the salary of the director and his necessary expenses. Dr. Linsly R. Williams was appointed director and began his work on Jan. 1st, 1924.

The scope of the Academy has grown steadily since it was founded in 1847, primarily for the purpose of providing a reading-room for its members. The reading-room gradually developed into a large library, and at the present time there is a membership of 1450 resident fellows, and some hundreds of non-resident fellows, associates, and honorary fellows. At present the Academy is housed in a five-story building at 17, West 43rd Street, and in this building maintains a library, which is the second largest medical library in America, consisting of 136,000 volumes and 20,000 pamphlets. It is open to the Fellows of the Academy and during the morning to the general public, and is used by 30,000 readers a year. The Fellows of the Academy hold two stated monthly meetings which are devoted to scientific purposes, and a dozen different sections meet on the various specialties in medicine once a month during the winter. There are also several special lectures held during the year. The Academy is also the meeting place of the County Medical Society and of dental societies and medical associations of various types. It also provides office quarters for the Medical Society of the State of New York and a number of physicians' aid associations. There are also special committees appointed—one on the library, one on education, and one on public health. The work of the committee on public health has recently received notice in our columns. The committee on education directs the work of two former societies—the Society for the Advancement of Clinical Study and the Society for the Advancement of Medical Education. This committee maintains a bureau of clinical information which announces daily the list of operations to be performed in the various hospitals of New York City, and also gives information as to the various post-graduate courses which are open to the post-graduate students in this city. This work, which has only recently been organised, seems likely to develop in a way more or less similar to the post-graduate education which is being carried on under the auspices of the Royal Society of Medicine in London.

CONGENITAL MEGACOLON.

IN THE LANCET of August 2nd we drew attention to a case of this disease communicated to the Medical Society of Hospitals of Paris, in which the distended loop was of enormous dimensions. A monograph of 243 pages has just been published by Dr. G. Tonnini,[1] professor of surgery at the hospital in Mondolfo, which, besides a very complete bibliography and report of a case under his own care, contains a tabular analysis of the 62 cases hitherto published by Italian observers such as Mya and Concetti, who strongly supported Hirschsprung's original conception of the congenital nature of the affection, contributing by their researches, especially in the field of histology, to complete the anatomical picture of megacolon and to explain the changes which are peculiar to this disease. If the much-discussed theory of Hirschsprung is at the present day recognised as true for a certain limited number of cases of dilatation of the large intestine, this is due in a large measure to the validity of the arguments brought forward by Italian authors. To prove this is the task Prof. Tonnini, with the coöperation of Profs. Simonini and Schiassi of the University of Modena, has set himself to perform. A reference to the 62 cases published in Italy shows that there was incontrovertible evidence of congenital origin in the sense expressed by Hirschsprung and Mya, from (*a*) previous history and clinical and anatomical data 22 cases, (*b*) history and clinical data 5 cases, (*c*) clinical and anatomical data 14 cases, and (*d*) from anatomical data alone 5 cases. Five cases seemed to support the contention of Marfan, Neter, and others as to the ætiological part played by unusual length, multiple folds of the iliac, sigmoid, and recto-colic kinks. In two cases only was there definite mechanical obstruction, while in nine it was found impossible to assign any causation. This little work may be said to contain all that has been written up to the present time concerning megacolon, and will well repay perusal.

DERMAL MYIASIS AND THE TUMBU-FLY IN SIERRA LEONE.

THE prevalence of myiasis from the Tumbu-fly in Sierra Leone is very considerable, causing much discomfort to man, suffering and even death to domestic animals. The Tumbu-fly, *Cordylobia*

---

[1] Megacolon Congenito. Premiata cooperativa tipographi, Modena. 1924. Pp. 243.

anthropophaga, has been indicted as the cause of painful boils for the last 60 years, when the disease was first investigated in Senegal, and the life-history and habits of this mysterious fly and its flesh-eating maggot have recently been worked out by B. Blacklock and M. C. Thompson at the Sir Alfred Jones Research Laboratory in Sierra Leone.[1] The *C. anthropophaga* in the adult stage averages about 9½ mm. in length, and is straw-coloured, with darker wings. The male can be distinguished by the approximation of its eyes. In habitat it is widely, though irregularly, distributed in West Africa from Senegal and Lake Chad to the Cape south of latitude 16° north. In Freetown the adult fly can be captured indoors during the dry season from November to April, and when disturbed it flies rapidly, emitting a loud buzzing noise. The bionomics of the insect, hitherto very uncertain, are described by the authors. The female fly deposits the ova by preference in sand, the number of eggs deposited varying from 200 to 300, while the life-span of the adult insect appears to be about 18 days. The larva, when newly hatched, is just visible to the naked eye and presents several interesting adaptive structures, such as a cephalo-pharyngeal skeleton and several cuticular spines which assist in penetrating the unbroken skin of the host. At this stage the larva remains just below the surface of the sand, but on being disturbed emerges, and when it has reached the skin of its disturber quickly crawls to the nearest wrinkle and commences to bore its way in. The larva undergoes three stages of moulting, and precise experiments indicate that in the second and third stages it is unable to penetrate the tissues to the same degree as the newly-hatched maggot. Further, when the larva in the second or third stage is removed from its cavity in the skin, it is not always able to regain its original position. Prior to pupation the mature larva leaves the tissues of its host and, falling into sand, rapidly burrows into it. The puparium, 6·5–11·5 mm. in length, has a characteristic shape. Pupation lasts about ten days, and on emergence the adult fly has undergone four ecdyses, of which the last occurs inside the puparium. The animals most frequently affected in nature are rats, in the burrows of which puparia are commonly found; other animals, such as dogs, cats, and squirrels, are liable to be attacked. As regards man, some interesting observations are recorded suggesting that after a primary myiasis a considerable degree of immunity to subsequent infection may be developed. The best form of treatment appears to consist in spreading a film of liquid paraffin over the opening made by the larva in the skin, after removing the scab. The posterior end of the larva immediately begins to emerge, and the film is then thickened by the addition of more paraffin. Pressure exerted on both sides of the cavity will then expel the parasite. It is interesting to note that the uneducated natives of Senegal have long been able to distinguish the life-history of the Tumbu-fly from that of the Congo floor-maggot (*Auchmeromyia luteola*). These two flies are very similar to each other in appearance, but the natives are aware that in the former case the larvæ live in the tissues of the host and produce boils, whilst the latter, living in the ground and emerging at night, merely feed on the blood of their victim.

WELFARE OF THE BLIND.

A Bill which will come before Parliament after the recess proposes to give a pension to every blind person at 30 years of age, to provide him with a minimum wage, and to ask the State to make a grant in aid of the continuity of his employment. Already the Blind Persons Act, which the proposed Bill is to amend, has reduced the pensionable age for blind persons to 50, and has subsidised schemes of training for industrial employment. Opinions among the blind themselves differ as to the wisdom of these measures. An organisation known as the National League of the Blind, waiting on the Minister of Health on July 31st, urged him to accept the amending Bill and pressed for the abolition of the voluntary system on which the provision of training facilities is at present largely dependent. On the other hand, the National Union of the Professional and Industrial Blind, through another deputation received by the Minister of Health in the same week, strongly objected to the amending Bill. To reduce the age for pensions from 50 to 30, it was stated, would place difficulties in the way of a really effective training being given. Since the productive capacity of the average blind worker was not more than 50 per cent. of that of the normal artisan engaged in the same occupations, the fear was expressed that the new proposals would increase the reluctance of local authorities to speed up methods of training, with the result that the number of employable blind persons would be actually decreased. The blind themselves considered, it was said, that far better results could be got out of the present machinery. The case is one for the legislature to consider carefully from all sides. The spirit of independence which we associate with the blind workers trained at St. Dunstan's is an asset to the community not to be lightly put in jeopardy. Blindness is not the only disability for which the sympathy of the public is called for, and if special privileges for one class of the partially disabled are provided, it is likely that complaints will be heard from other quarters. Moreover, the line to be drawn between the blind and the not-blind is no hard-and-fast one. "Too blind to carry on his ordinary employment" may be a good enough definition for the purpose of a certificate, but certainly not to confer a definite legal status. Nevertheless, for purposes of legal privilege it is necessary to draw the line somewhere; and if a man of 30, whose sight is no better than finger-counting at 20 inches, is to claim a pension, another who can count up to 30 inches may feel aggrieved if nothing is done for him. The difficulty does not loom nearly so large when pensions are not given until the age of 50 as it would if the age were reduced to 30. We agree with the National Union in doubting whether the Bill to amend the Blind Persons Act would amend the lot of the blind.

HOUSEWIFERY IN A HOSPITAL MILIEU.

An unusual enterprise on the part of a voluntary hospital is announced by Lord Hambleden—the institution under the auspices of King's College Hospital and in its grounds of a school where young girls may receive a ten weeks' course of instruction in the domestic arts and in elementary nursing. The curriculum outlined appears well adapted for its purpose of providing a term of practical instruction in housewifery to follow school life. During the first seven weeks pupils will be instructed in all branches of the work of running the house of residence which they are to share with the pupil nurses undergoing preliminary training. They will also have lessons in cookery, including food values; elementary anatomy and physiology; hygiene, including elementary chemistry of common things; elementary and minor medicine and surgery; the application and making of bandages and surgical dressings; and elementary nursing. For the final three weeks the pupils will be permitted—apparently as a privilege—to take some practical part in the work of the hospital, in the kitchens, housekeeping departments, and the out-patient or casualty departments, but will not be allowed in the wards. The terms for the ten weeks' course will be thirty guineas, inclusive of board residence. It is not clear with what exact object King's College Hospital has decided to enter into competition with the various existing schools of domestic economy where short courses of training on broadly similar lines are given. It may well be that the institution is designed to be a source of pecuniary profit to the hospital, since, besides paying fees, the pupils will be taking the place of paid domestic help in the pupil nurses' home. There would seem to be no danger of the pupils being exploited indirectly for the benefit of the hospital, since only three weeks' participation in its work are to be allowed. Lord Hambleden states that "the intention is to provide a practical course which will be useful to a girl who may have no thought whatever of becoming a nurse, but desires to gain some useful knowledge and, perhaps, to appreciate some of the joy of service." The first of these inducements is more likely to attract girls now leaving secondary or public schools than the second, since the imagination of the modern girl is unlikely to be touched by the glamour which formerly surrounded hospital life. The course should, however, prove attractive on its merits. Instruction as to how to achieve and maintain the high standard of household cleanliness current in our great hospitals will be welcomed, and, moreover, the teaching on subjects ancillary to medicine is likely to be of more practical use than the corresponding courses at the majority of domestic economy schools. The proposed social intercourse between the pupils and the nurses engaged in the hospital work should lead to a useful interchange of ideas between those paying in money for a brief course of instruction and those paying in prolonged service for a complete training. Girls whose direct activities in the hospital are arbitrarily limited to three weeks' sporadic work in the kitchen or out-patient department may envy those who have free access to the mysterious fascinations of the wards, and in this way recruits to the nursing staff may be obtained. It is also possible that critical young eyes may detect and protest against those defects in our system of training nurses which the Rockefeller Commission set out so clearly. But we are assuming an intimacy of association between nurses already in hospital and pupil housewives which the common tennis-courts and dining-room described by Lord Hambleden will hardly ensure, and it is more probable that the two communities will not, in the American phrase, prove good mixers. We shall watch the development of this new school with much interest.

[1] A Study of the Tumbu-fly (*Cordylobia anthropophaga*), Grünberg. Sierra Leone. By B. Blacklock, M.D., and M. C. Thompson. Annals of Tropical Medicine and Parasitology. Vol. xvii., No. 4, Dec. 21st, 1923.

SCHOOL CLOSURE FOR INFECTIOUS DISEASE.

THE Board of Education has issued a circular to local authorities proposing to amend the Elementary Education Provisional Code, 1922. The lines on which the alterations are to be made are indicated in the circular, where it is announced that the whole matter will be further discussed and explained in detail in a revised memorandum on closure of schools and exclusion from school, to be drawn up under the joint auspices of the Board of Education and the Minister of Health. The main point of alteration evidently deals with the question of school closure. The Board of Education has now come to the conclusion that the best means of preventing a spread of infection during an epidemic is not the closure of whole schools or departments, but the careful consideration of individual children. Such closure is, the circular states, rarely justified on the grounds of health, while on educational grounds it is obviously desirable that schools should remain open. We have in these columns long advocated the watching of individual cases rather than the blind policy of school closure, and now that school closure as a means of preventing financial loss is no longer to be authorised, urban schools throughout the country should become, as they have been in London for the last 15 years, the centre for scientific control of infectious disease. Rural districts with a scattered population present quite a different problem. Control of infection here more often than not is got by prompt closure and notification, and it is to be hoped that special consideration on helpful lines will be given to this point in the revised edition of the code. The circular is welcome evidence that at the Board of Education questions of hygiene receive sound contemplation.

FUR DERMATITIS.

DURING the latter part of the winter 1922–23 a number of women and girls attended hospitals on account of a local irritation around the neck which soon went on to a blotchy erythema and in neglected cases to a condition of chronic eczema. Hundreds of such cases were reported, none of them fatal. Dr. J. H. Sequeira was the first to associate the condition with the wearing of a kind of rabbit skin dyed to resemble beaver, and careful investigation conducted by Prof. A. G. Perkin identified the irritating substance as paraphenylene-diamine or the closely related metaphenylene-diamine. The dyes used were of foreign origin, careless technique having omitted to render the dyed article innocuous by subsequent oxidation. Dr. J. W. Eyre failed to find any pathogenic microbes which could be associated with the causation of the dermatitis. The report[1] by Dr. Allan C. Parsons, just issued by the Ministry of Health, gives an admirable summary of the history of this dermatitis and the stages by which its origin, its distribution, and its causation were worked out to a final conclusion. Two factors determined the incidence, for since only a relatively small number of fur-wearing individuals were affected it was evident that personal susceptibility played a part, and this susceptibility proved to be specific for a certain class of fur. While symptoms sometimes appeared a few hours after contact, in most cases there was a definite latent interval of 2–6 weeks or more between the wearing of the fur and the first signs of reaction. It is satisfactory to be assured, on the authority of the London Fur Trade Association, that the epidemic was exclusively due to foreign dyes and that makers at home had no responsibility for its production. The publication of the report will no doubt ensure the non-recurrence of an avoidable disease.

IN response to the appeal of the Cambridge University authorities for the sum of £33,000 to complete the endowment of a School of Pathology, Mr. Ernest Gates, of Milner Field, Bingley, Yorks, has promised to provide the required amount. The trustees of the Rockefeller Foundation recently offered to provide the University of Cambridge with £100,000 to build a School of Pathology, together with the sum of £33,000 towards its endowment, on condition that the University could obtain a further £33,000 for this purpose. Mr. Gates's generous gift now makes the acceptance of the Rockefeller offer possible.

[1] Reports on Public Health and Medical Subjects. No. 27. H.M. Stationery Office. 1924. 9*d.*

THE Manager of THE LANCET would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

STRASBOURG FACULTY OF MEDICINE.—A complete practical course of dermatology and venereology will be held at the Clinic of Syphilitic and Skin Diseases in Strasbourg, from Sept. 22nd to Nov. 8th, under the direction of Prof. Pautrier. The course will consist of 57 lectures in dermatology and 42 lectures in venereology, accompanied by a demonstration of patients and lantern-slides. In connexion with the skin clinic there is a library of 3000 volumes, which will be available to those attending the courses. The enrolment fee is 200 francs. Fuller particulars may be obtained from Prof. Pautrier at the Medical Faculty of Strasbourg.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXVI.—TREATMENT OF ESTABLISHED TABES.

No account, however brief, of the treatment of tabes would be adequate without its preface. Within the central nervous system nerve fibres, once their continuity is interrupted by disease, are incapable of regeneration. Though it may be possible by suitable treatment to prevent further extension some irreparable damage will remain. Hence the overwhelming importance of *early* diagnosis. The diagnosis being made, treatment may be considered under the headings General Régime, Anti-Syphilitic Treatment, and Symptomatic Treatment.

General Régime.

The general principle is to be inculcated that the damaged machinery should not be overloaded. Exertion, mental or physical, should never be pushed beyond the point of fatigue. Since in addition to those nerve fibres which have been already destroyed by the disease there are others whose function is barely maintained and whose continuity, as it were, hangs on a thread, substances which are known to have a deleterious action upon the nervous system should be used with strict moderation. Of these the most important are alcohol and tobacco. Exposure to cold and wet, even if it has no influence upon the course of the disease, may certainly provoke an exacerbation of lightning pains, and is therefore to be avoided. Finally a special caution must be given against excessive sexual indulgence, which, in the experience of most clinicians, has at times been immediately followed by signs of increased damage to the cord.

Anti-Syphilitic Treatment.

Tabes is a late result of a generalised infection by the *Spirochæta pallida*, which has been demonstrated post mortem in the spinal cord and posterior nerve roots of cases of the disease. The symptoms of the illness are due to irritation and destruction of nerve fibres; the progress of the disease is caused by the continued action of the spirochætal poison. Adequate treatment by means of spirochæticidal drugs may fairly be expected to arrest this progress. The tried remedies of this nature at our disposal are arsenic, mercury, and potassium iodide. Of these there is no doubt that arsenic is the most effective; the value of mercury is more doubtful. The late Sir William Gowers expressed the opinion that in cases of tabes energetic mercurial treatment such as was given at one time at Aix-la-Chapelle only did harm. Potassium iodide certainly has not the same favourable influence upon the course of tabes as it has upon meningeal and vascular syphilis. Nevertheless, since both mercury and potassium iodide appear to be effective in syphilis elsewhere in the body, and we are dealing with a generalised syphilitic infection, both these drugs may be given concurrently with arsenic, provided that the doses employed do not upset the patient in such a way as to interfere with the administration of full doses of the more important drug. In this as in other matters the tolerance of the individual patient must be studied. I have met with cases in which the combined course of treatment resulted in malaise and anorexia: yet when the mercury and iodides were withdrawn the patient tolerated full doses of arsenic without discomfort.

Of the three methods of injecting arsenic—intravenous, intra-muscular, and subcutaneous—the intravenous route is to be preferred on practical as well as upon theoretical grounds, provided that the patient has veins suited to the purpose. The practical advantage of this method is its freedom from all pain save the immediate prick of the puncture. In theory it provides the most effective means of submitting the causal organisms of the disease to the immediate influence of maximal doses of the drug. Clinical experience supports this hypothesis, for in cases which eventually show good results from treatment, the first intravenous injections are commonly followed within 24 hours by an exacerbation of symptoms, such as lightning pains or visceral crises, probably indicating a focal reaction to the treatment. The fact that intravenous injections are more liable to produce symptoms of an immediate "toxic" reaction in the patient than subcutaneous or intramuscular doses is no objection to their use. Animal experiments have shown that the germicidal action of arsenobenzol compounds upon an infecting protozoon is roughly proportional to their toxic action upon the host, so that within the limits of safety[1] "toxic reaction" in the patient may be taken as evidence of efficient dosage.

Of the various preparations of arsenic suitable for intravenous injection that known as novarsenobillon best combines simplicity and efficacy, being readily soluble and easy to administer. A dose of 0·9 g. N.A.B. in 10 c.cm. of distilled water gives a perfectly clear solution. Experience has shown that certain unpleasant symptoms such as headache, fever, and shivering which occasionally follow within 24 hours of an injection may be due to the presence of dead bacteria in the water used for the solution. It is therefore advisable to use for this purpose ampoules of distilled water which has been sterilised and sealed immediately after distillation. Such ampoules, containing 10 or 20 c.cm., are easily obtainable. The technique of intravenous therapy lies beyond the scope of this article, but in view of the fear of a "bad arm" after injection, which is sometimes a bar to efficient treatment, two points may be noted. First, the vein to be easily pierced must be adequately compressed, and this is most simply done by applying the pneumatic band of an ordinary sphygmomanometer and blowing it up to a point just insufficient to obliterate the arterial pulse. In the second place the least sign of leakage into the tissues at the commencement of injection should be the signal for withdrawal of the needle and puncture of another vein. Upon the question of dosage no hard-and-fast rules can be laid down. Individual symptoms and individual tolerance have to be considered in each case. The following plan is suitable in the case of a male adult who tolerates the treatment well.

A mixture containing ʒi of the liquor hydrarg. perchlor. and 30 gr. of pot. iod. is given three times daily from the onset. The course of arsenical treatment begins with an injection of 0·45 g.; after a week's interval 0·6 g. is given, and subsequently doses of 0·9 g. at weekly intervals until approximately 5 g. have been given. An interval of six weeks is then allowed during which the mixture is continued, but no arsenic is given. In practice this has been found a safe period to allow for the prevention of cumulative arsenical poisoning. The injections of 0·9 g. are then continued at weekly intervals until a further 5 g. have been given. At the end of this course the patient is allowed six weeks' freedom from all drugs; the mixture and injections are then begun again until a further 5 g. of N.A.B. have been administered, and the patient continues with the mixture for a further six weeks.

Further treatment will depend upon the state of the disease. In the great majority of cases progress will have been arrested, and symptoms in some degree relieved; in this case the patient may be released with the advice to attend for further treatment if fresh symptoms develop, and *in any case* to attend annually for a short course as a preventive of further trouble. This course should consist of four weekly doses of 0·9 g. N.A.B. together with mercury and iodide by the mouth as before.

---

[1] Safe preparations are those which bear a label stating "The contents of this box have passed the tests of the Medical Research Council for toxicity and therapeutic activity."

The results of anti-syphilitic treatment carried out upon these lines are encouraging. In the majority of cases the progress of the disease is brought to a standstill; the severity of lightning pains and visceral crises also is frequently mitigated. Some few cases, however, in spite of treatment progress from bad to worse, so that no absolute assurance of relief can be given to a patient. In these cases anti-syphilitic treatment should be continued so long as the patient develops no symptoms of intolerance. Most tabetics bear well the dosage of N.A.B. described. A careful watch must be kept for individuals intolerant of arsenic; for since the poison has a cumulative effect, severe toxic symptoms may continue to develop for several weeks after the last injection has been given.

The W.R. in blood and spinal fluid is often valuable in confirming a diagnosis of early tabes. As a guide to progress and further treatment it is unreliable, since it is by no means rare to discover actively progressing tabes with a positive history of syphilitic infection despite a negative reaction in both blood and fluid. As to the intrathecal injection of salvarsanised serum, the theoretical basis for its use is insecure, it is a complicated, costly, and painful procedure, and there is no certain evidence to show that the clinical results achieved by it are better than those which may be expected from intravenous injections alone.

Symptomatic Treatment.

The severity of lightning pains may be mitigated by means of the coal tar analgesics. Veramon in doses of 6 to 12 gr. is especially useful. Opium should be reserved for rare occasions, as when it may be essential for a special purpose that the patient should obtain complete relief for a few hours.

Gastric crises, if the patient is capable of taking drugs by the mouth, may be partially relieved by the administration of chloretone in 10 gr. cachets (two or three in 24 hours) or an attempt be made to abort the attack by a single dose of 20 gr. Tr. belladonnæ in 10 ♏ doses also has a favourable effect in some cases. Failing these remedies morphia judiciously administered by a nurse at critical periods affords the only measure of relief. In a prolonged attack, warmth, rest in bed, and rectal glucose are essential to combat the prostration. In long-standing cases recourse may be had to operation. Posterior root section is seldom of permanent value; more favourable results have followed section of the pain tracts in the spinal cord, a more delicate but less severe operation than the other.

Bladder disturbances may be of two kinds. Spasmodic evacuation with imperfect control may be relieved by tr. belladonnæ in 5 ♏ doses thrice daily. Atony of the bladder wall with retention may be combated with a similar dose of liq. strychninæ. In either condition the patient should be instructed to attempt to pass water at regular (three hourly) intervals regardless of desire. Retention with overflow calls for regular catheterisation and a daily wash out with 1/2 per cent. acetic acid. The ataxia may be partially compensated by means of the exercises originally suggested by Frenkel. These may be commenced in bed, and with their aid it is sometimes possible to obtain some power of locomotion even for patients long bedridden.

Perforating ulcers are more easily prevented than cured. The tabetic should be warned never to cut his corns. Charcot's joints in the acute stage should be treated by rest and immobilisation. In the later stages celluloid splints may be of great value in preventing excessive mobility (especially at the knee-joint) without overburdening the limb.

C. P. SYMONDS, M.D. Oxf., F.R.C.P. Lond.,
Assistant Physician for Nervous Diseases, Guy's Hospital.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

(Continued from p. 398.)

SECTION OF PATHOLOGY AND BACTERIOLOGY.

WEDNESDAY, JULY 23RD.

AT the opening session, the President of the section, Prof. CARL BROWNING, being in the chair, Dr. ALEXIS CARREL (United States) read a paper on

Tissue Culture.

Dr. Carrel said that his interest in the healing of wounds and the rate of cicatrisation had led him to take up tissue culture as a means of approaching the elementary principles of the problem. The earlier work of Ross Harrison was important as being that of a pioneer, but the technique was rudimentary and the cultures impure. More recently methods had been devised which enabled pure strains of certain tissues to be obtained and to be cultured indefinitely. When this had been achieved it was possible to proceed to the study of the rate of growth and the exact measurement of various factors influencing growth. Pure cultures could be obtained by one of two methods. The first consisted in taking advantage of the greater rate of proliferation of certain tissues—e.g., fibroblasts—which in the course of time outgrew other tissues with which they might in the first instance be admixed. In like manner in a mixture of blood-cells the ultimate survivors were the large mononuclear cells which outgrew the other elements whose vitality was of a much lower order. The second method depended upon the selective action of certain media; thus leucocytes of the large mononuclear type grew well in serum, but poorly in embryonic tissue juices, whilst the converse held for fibroblasts. Once pure cultures had been obtained the labour of keeping them growing was very great since it necessitated frequent subculture, preceded by washing the fragment used in Tyrode's solution. An alternative method had been devised which was of great use in this connexion and consisted in embedding the fragment of tissue under cultivation in some solid retaining medium placed in the bottom of a small glass capsule, with the nutrient fluid floating above it; with such an arrangement the fluid culture medium can be changed every two to three days and the tissue may remain growing and undisturbed for from 15 days to a month. Utilising technique of the variety described Dr. Carrel had maintained chicken fibroblasts for as long as 12 years in active culture, a period which is in excess of the normal life of the animal from which the tissue had been derived. Preparations were exhibited of large mononuclear cells, squamous epithelium, and thyroid epithelium, all of which had been successfully cultivated.

Dr. Carrel had directed his attention particularly to the rate of growth of various tissues and the factors influencing this, and described the method adopted for estimating it. Tissues were endowed with a certain residual growth energy which enabled them to proliferate and live for some time after removal from the body if placed in a neutral medium. This was not true growth, but depended upon factors carried from the parent body into the medium which after a time became exhausted; this feature was more noticeable in embryonic than in maturer tissues. In like fashion the growth-stimulating substances present in the tissues, serum, and body juices were more active in young animals than in older, and the same factor, controlling tissue growth, seemed implicated in the processes of cicatrisation in the body.

Up to the present time Dr. Carrel and his staff had been largely occupied in overcoming technical difficulties and ascertaining what conditions would give the best results. Their investigations of the large field which these methods opened up was only now beginning. Certain principles had begun to emerge from a mass of experimental data amongst which he would mention that it had been established that the growth energy of cells in vitro was mainly a function of the medium used. Given a suitable medium the fibroblasts of the chick could be grown indefinitely and were immortal. Serum was not a generally suitable medium, but a selective one; it inhibited the multiplication of fibroblasts and epithelium, but not of large mononuclear phagocytes. Plasma alone was not a nutritive medium; certain additional factors, present in embryonic juices, were necessary to promote growth, and in the earlier work of Ross Harrison and others true growth was not present, only survival of the tissue implanted. It had been possible to demonstrate the secretion of cells upon a small scale, notably with leucocytes and the thyroid epithelium. The promise of this method of attacking the problems of biology and pathology was enormous, and at the present time the way was open for the examination of numerous problems; the difficulties, which must not be misunderstood, were mainly those of technique. What was wanted were improvements which would enable tissue cultivation to be carried on not only with the ease with which bacterial cultivation is carried on, but upon a large instead of a microscopic scale. Dr. Carrel was full of hope that these difficulties would be surmounted. At present the number of workers in this field was small, but he hoped that others would take it up, and he looked forward to new ideas and extended results which would follow when more workers brought their interest to bear upon the problems he had discussed.

Dr. S. **RICART** (Barcelona), who had learned the technique of tissue culture from Dr. Carrel, referred to the importance of the work of the American biologists in this field. He had studied tissue culture and found the difficulties present to be entirely those of technique; once this was simplified the difficulties would be mastered. The life of cultivated tissues was precarious in proportion to the specialisation of the tissues; fibroblasts alone could be cultivated indefinitely. The growth in any case varied with the composition of the medium and was not controlled by other factors. Cells which did not survive underwent fatty degeneration and disintegration. The method had been applied by him to the examination of antiseptics and the comparison of their antiseptic effect with their deleterious action upon the tissues.

The **PRESIDENT** commented upon the fibroblast-like appearance of the macrophages in some of Dr. Carrel's preparations. With him it had been an article of faith that under certain conditions fibrous tissue cells might become undifferentiated so as to resemble mononuclear cells, but the possibility of the converse taking place had hardly been accepted. The disappearance of polymorphs from a culture of blood elements was comprehensible as the polymorph was the finished product of a definite life-cycle, but it would be interesting to know what would be the fate of its precursors—e.g., myelocytes—in like circumstances. With regard to the increase in amount of growth, he suggested that increase in weight would be the best criterion, if that could be measured.

Mr. C. J. **BOND** asked how the pH of the media used was determined and how it was regulated.

Dr. J. H. **DIBLE** said that the speaker had mentioned the necessity of certain substances derived especially from embryonic tissues as stimulating and essential factors for the growth of culture. He asked if anything was known of the biological properties of these substances; were they heat-stable, could they be preserved, or were they labile substances like complement?

Dr. T. G. M. **HINE** and others asked for details of the composition of Dr. Carrel's media. As made up from published formulæ it was not always satisfactory and sometimes acid, requiring added alkali to reduce its reaction. Dr. Hine had used oxalated plasma and thought it had an antiseptic effect.

Prof. M. J. **STEWART** said that as one unfamiliar with the technique he was greatly impressed by its possibilities in bearing upon a number of pathological problems. He would like to ask what was the relative phagocytic activity of fibroblasts and macrophages in vitro; also if neuroglia was possessed of any powers of growth and phagocytosis, especially as it possessed the latter faculty to a marked degree in some brain degenerations. He further asked for information as to the behaviour of fibroblasts and epithelium when grown side by side.

Dr. J. E. **MCCARTNEY** said that he had seen Dr. Carrel working in the Rockefeller Institute and was greatly impressed by the technical difficulties in carrying out this work. He mentioned that success or failure might depend upon the quality of the glassware used, and suggested that the method might be of use in the study of filtrable viruses.

Dr. J. **CRUICKSHANK** spoke of the results which had been achieved by Dr. A. H. Drew, and mentioned that he was carrying out tissue cultures by the same technique. It was exceedingly important to use pure chemicals. Rat and mouse tumours grew well, and kidney tissue perhaps best of all. He had been impressed by the fact that to grow the fragments of tissue had to be supported in some way, floating fragments showed no growth. He did not quite appreciate the distinction made by Dr. Carrel between growth and survival. If mitotic figures and cellular increase were observed, did not that constitute growth?

Reply.

Dr. **CARREL**, replying at some length, said that he had never succeeded in cultivating polymorph leucocytes; in cultures made from mixed blood elements they always underwent phagocytosis by the mononuclears. The change of the mononuclear to a fibroblast-like form was not a usual one, but only occurred under special circumstances connected with stresses occurring in the coagulated plasma in the medium. He did not know if it was possible to produce a variety which perpetuated this morphology in culture. Replying to Mr. Bond, the H·ion concentration of the medium had to be between 7·4 and 7·8 on the pH scale. Colorimetric methods were used for its estimation, and the condition of all media was tested daily prior to their use.

The nature of the growth-stimulating substance derived from fœtal tissues had been the subject of much inquiry, and its exact nature was still unknown. They had learned, however, that it is an unstable substance, disappearing in a few days at 37° C. and more rapidly at higher temperatures. It is precipitated from solution by protein precipitants and appears to be a nucleo-protein, but cannot be replaced by any known substance of this nature. With regard to the media, a great variety may be used, plasma being the one best suited for stock cultures. The chemicals used must be absolutely pure and the distilled water above suspicion. The refractive index and pH of all solutions was estimated daily in his laboratory prior to their being used. In answer to other questions, he stated that phagocytosis by fibroblasts was very slight, but that shown by mononuclear leucocytes was marked. The cultivation of neuroglia had not been undertaken. With regard to his definition of growth, the presence of mitotic figures and cell multiplication did not mean growth in his sense; there was enough nutritive substance existing in a newly planted fragment of tissue to allow this, and the tissue might live and, in the case of heart muscle, pulsate for a long period and yet show no actual growth, as the fragment gradually underwent progressive diminution. By growth he meant the fabrication of new cells wholely and solely from the constituents of the culture-medium, and increase in the mass of the culture. Weighing the tissue was the ideal way of determining this, but at the present stage it was a technical impossibility.

Mr. A. **MALINS SMITH** read a paper upon the occurrence of

Protozoal Infections of the Bowel

in inhabitants of this country. He had found *Entamœba histolytica* cysts in a certain number of persons, and had succeeded in infecting kittens with dysentery from their stools. These persons had never been out of this country. In the examination of a total 2137 persons of different ages, 3·4 per cent. were found to harbour *Entamœba histolytica*. In many of these cases further investigation showed the infection to be a familial one. Dr. Smith concluded that the presence of *E. histolytica* does not necessarily connote dysentery in the clinical acceptance of the term, but thought that a balance of tolerance might be arrived at between the parasite and the host which was capable of being broken down in favour of the parasite by adventitious circumstances.

Dr. C. E. Dukes demonstrated a modification of the sigmoidoscope, for obtaining direct cultures from the intestinal mucosa in cases of ulcerative colitis.

Thursday, July 24th.

At the second session the chair was taken by Dr. A. G. Gibson. Dr. R. A. O'Brien opened a discussion on

Immunity, with Special Reference to Specificity and the Influence of Non-specific Factors.

He said that his contribution to the discussion was directed from the view-point of the laboratory worker whose daily occupation was the carrying out of rigorously controlled experiments, in connexion with the production and testing of sera, vaccines, tuberculins, and other biological products, which necessitated a keen watch for the intervention of any disturbing non-specific factors. Such tests as these were fundamentally dependent upon the rigid doctrine of specificity, which was at the basis of diphtheria antitoxin production, gas gangrene antiserum, and tuberculin and pneumococcal antiserum manufacture. Non-specific factors were encountered in the Wassermann reaction, the agglutination of *Proteus* X 19 in typhus fever, and in the Forssman phenomenon in hæmolysin production.

When an animal was immunised, the resulting production of antibody was a matter which was continued over an extended period and apparently went on after the stimulus of the antigen had ceased, presumably by a continued action of the body cells. It had recently been asked if such output of antibody might not be stimulated by non-specific means: this view had been put forward notably by the Copenhagen workers who claimed to have stimulated the production of diphtheria antitoxin by injection of manganese chloride. In the hands of the speaker and his colleagues no such results had been obtained, and in like manner peptone injections had given negative results. At the same time a certain amount of evidence existed that the phenomenon of antibody production was susceptible of being controlled or directed into certain channels by the simultaneous presence of more than one antigen. As a result of many experiments no evidence was forthcoming that non-specific agents either caused a release of antibodies or in any way modified the course of acute experimental infections. The clinical standpoint was one much harder to evaluate as the conditions of laboratory experiment could hardly be reproduced here, and the psychological factor was a disturbing one. The physician was faced not only by the problem of ascertaining the true result of his experiment, but by the more urgent one of curing his patient. There seemed, however, to be a considerable weight of evidence in favour of some good results being achieved by *non*-specific therapy in asthma, hay fever, and allied conditions. The matter was one for further development, and however little it appeared in accord with our present rather rigid views of specificity, the lesson of Loeb's "fatherless frog" must warn us against too ready incredulity.

Dr. P. Hartley spoke especially of the chemical aspect of the question. He emphasised the enormous degree of specificity associated with the immunity reactions in certain directions, which far out-distanced chemical methods of investigation—e.g., in the differentiation of proteins. The matter was, however, closely allied to the chemistry of the proteins, which alone caused the immunity response and gave the immunity reactions. The two explanations of the phenomena in the field were Ehrlich's chemical conceptions and the more modern physical ones, which, however, failed completely over the question of specificity. When proteins, such as sera, were submitted to ordinary chemical analysis, and their amino-acid constitution investigated, such immunologically different varieties as ox and horse serum gave identical results. When serum was split up into its albumin and globulin fractions a difference appeared between the two fractions, involving mainly the cystine and lysine distribution, but no difference could be noted between euglobulin and pseudo-globulin. Euglobulin was probably pseudo-globulin plus the lipoids of the serum. When studied immunologically, however, the albumin and globulin fractions were sharply different, and there was also well-marked differentiation of the globulins, although there was here some overlapping. Evidently ordinary chemical resolution into the constituent amino-acids did not therefore throw any direct light upon the problem of immunological specificity, and the present-day tendency was to look to the internal structure of the protein molecule as a more profitable subject for examination. The procedure of protein racemisation altered the biological characters of the protein used, and these changes were found to be associated with changes in the optical activity of certain of the constituent amino-acids when the proteins were subsequently hydrolysed. Thus, proteins of the same chemical composition, such as caseinogen from two different animals, when split up after such treatment might resolve in different ways, the resulting products not being identical, and the suggestion was made that these differences might be at the basis of specificity. Some recent work by Avery and Heidelberger had shown that from autolysed pneumococci of the immunological type 2, a soluble specific precipitin for type 2 antiserum might be extracted. This substance was peculiar from the point of view of the present problem in being an impure carbohydrate with only a very low nitrogen content. It would not stimulate antibody production although giving a specific reaction with the type 2 serum. This work appeared to open up a rather different field, and might aid in the resolution of the problem which appeared to be bound up with the chemical structure of the proteins, the most difficult of all the problems in pure chemistry.

Prof. T. J. Mackie spoke of the varied degree with which the problem of specificity applied over the field of pathology. Specific reactions in the case of typhoid were effective for all bacilli of this group, whilst in the case of *B. coli* it was a much narrower affair, being here generally an individual property of each strain. The possibility of stimulation of non-specific antibodies, which were known to exist, by heterologous antigens must be considered, as well as the effects on the general metabolism of parenteral injections.

The speaker went on to consider instances of non-specific effects which were well known, such as the stimulation of latent typhoid agglutinins in inoculated soldiers by some other infection. More striking were the recent claims made out for the stimulation of antibodies by chemical substances and especially those of Walbaum and Madsen for the enhancement of diphtheria antitoxin production by manganese chloride, which work was disputed by many observers. Personal experiments with hæmolytic antibody, on these lines, had given irregular and inconstant, but in certain cases definitely positive, results; the increase in hæmolysin being occasionally as much as ten times the original titre. The increase, when present, was a temporary one which disappeared in a few days. In other cases normal serum was found to have a weak non-specific protective effect against diphtheria toxin, especially in the case of the local lesions.

Prof. W. J. Tulloch said that there were two points of view of specificity—firstly, specificity in diagnosis, and, secondly, specificity *in therapeusis*, and that the debatable ground lay between these two standpoints. He believed that there were no structural differences between the types of antibody and that theoretically any of the immunity reactions might be used for diagnosis; which one was preferred was a matter of convenience. In many cases such diagnostic procedures were not specific and bore no relationship to immunity—e.g., in the Weil-Felix reaction for typhus and the modern Wassermann reaction for syphilis. There was too great a tendency to be blinded by the main and clamant facts in any case of disease, and to neglect the minor but contributory ones. Diphtheria was not solely an intoxication; there was the factor of infection also to be reckoned with. In this disease antitoxin was only a partial antigen, but fortunately it was effective. In studying disease the mechanism of infection must be considered, along with the mechanism of the production of lesions and of death, to obtain a comprehensive picture of it. In tetanus there is, besides the main toxic factor, the neurotoxin, a secondary though slight leucotoxic aggressin effect, which unlike the toxic factor is specific for the different agglutination types of the bacillus. Greater toxin specificity is illustrated in the botulinus group where the toxin is specific for each bacterial type. Agglutination reactions from the therapeutic point of view are, therefore, ultra-specific in tetanus and diphtheria, but intra-specific in tubercle. In meningococcal infections a middle position is probably the case, for here serological differences seem of therapeutical importance.

Dr. **Stanley Davidson** spoke on the alteration of the qualities of antigens by physical and chemical agencies, especially with reference to the effect of "detoxication" and "defatting," as suggested by D. Thomson and G. Dreyer, respectively. A large series of experiments was detailed in which the agglutinins and complement-fixing antibodies produced, in comparable series of animals, by these preparations were compared with those produced in response to the injection of ordinary killed bacterial suspensions. Rabbits were the animals used and *B. suipestifer*, a well-known pathogenic agent for the rabbit, the organism utilised. The results showed very strikingly the inferiority of the treated organisms as provokers of this class of antibody response; agglutinins, which were abundantly produced by the ordinary vaccine, being produced only by a few animals and in very small amounts where the defatted or detoxicated antigens were employed. The same was true, to an even more marked extent, in the case of the complement-fixing bodies. As regards actual protection, only one animal of the whole series survived the test dose, and this was one which had had the unmodified vaccine and had produced the greatest amount of antibody as estimated by in vitro methods.

Dr. D. **Campbell** spoke of the clinical aspect of specificity, and remarked that natural immunity was often due to factors quite other than specific ones in the sense used in the discussion. He also emphasised the fact that vaccine therapy was not now advocated in diseases in which the causal organism was well known, such as typhoid and pneumonia, but in obscure conditions in which the relationship of the disease to the organisms in the vaccine was extremely doubtful. He spoke on non-specific protein therapy in relationship to rheumatoid arthritis, and considered it the most valuable agent in the physician's armamentarium. The rationale of the treatment seemed in the production of a general reaction in which temperature, leucocytosis, and a possible mobilisation of enzymes played a part. The improvement which resulted was generally in correspondence with the degree of reaction which was provoked. Whilst not claiming that the method removed fibrous adhesions, or resulted in a repair of anatomical changes, he believed that it definitely resulted in an arrest of the progressive nature of the condition.

Dr. E. M. **Dunlop**, who had worked with Dr. Campbell, the previous speaker, said that typhoid vaccine was used in these cases. Detoxication damaged the antigenic properties of the vaccine, and its injection did not result in the production of agglutinins and complement-fixing antibodies. In certain cases rather untoward reactions had developed, but in one of these there was a suspicion of a previous typhoidal infection. There was no evidence that detoxicated vaccines would release antibodies in patients who had these in a latent state.

Dr. R. **Row** detailed some experiments upon the various fractions obtainable from tubercle bacilli. Complement fixation had failed in his hands with the waxy and ether-soluble bodies, but was generally positive with the non-acid-fast residue. Experiments on the antigenic value of these latter substances for guinea-pigs led to the view that they did somewhat increase resistance to subsequent infection. In cases of natives treated in India by injections of material of this sort some improvement was observable, especially in cases of glandular tuberculosis.

Prof. C. H. **Browning** stressed the importance of the individual factor in animal experiments as a point well recognised in the human subject but one generally overlooked in laboratory animals. There was a temptation to regard the animal too much as an unvarying reagent. He had been struck by the flat contradictions which the discussion of non-specific factors had brought out. Where competent investigators obtained different results it would be more profitable to pursue these investigations and seek out the causes of difference than to leave existing contradictions. Koch dogmatically stated, in his tuberculin researches, that he had cured his guinea-pigs, and up to the present time no explanation of these unconfirmed results had ever been forthcoming. Dr. Campbell had introduced the clinical aspect of the non-specific side of the discussion, and the speaker had seen many of these cases which had been spread over a long period, and from the point of view of an observer he had found them impressive. He also mentioned that Prof. Ralph Stockman, who was an exceedingly cautious and critical observer, considered the method the most satisfactory one in existence for the treatment of arthritis deformans. The discussion on immunity was a hardy annual in pathological circles, and he considered that the most promising fact of recent discovery in the field of immunity was that of the association of antigenic properties with non-protein substances.

Reply.

Dr. **O'Brien**, who replied briefly, said that he was strongly of the opinion that at the present time coöperation between the immunologist and the biochemist was of the greatest importance. Much of the clinical evidence adduced in support of one or other view of the therapeutic value of different methods of immunisation was utterly valueless, as the necessity for adequate control was not always realised upon the clinical side. He was impressed by Dr. Campbell's work and thought that a thorough investigation of other current methods of treatment upon critical lines, and over a sufficiently long period, would be of the greatest value.

Friday, July 25th.

At the third session the chair was taken by Prof. T. J. **Mackie**.

Prof. M. J. **Stewart** read a paper on

Xanthoma and Xanthosis.

He said that these conditions were due to an excessive accumulation of lipoids which were deposited in the tissues, in the first place in large phagocytic cells, which had a characteristic "foamy" appearance. He exemplified such local deposits by xanthoma diabeticorum, which was a local manifestation of a condition of hypercholesteræmia. The localisation of the tumours was probably determined by trauma, after which the effused and deposited lipoids were taken up by phagocytic cells. The condition was a persistent one, as might be expected, and disappearance of the cholesteræmia did not result in disappearance of the tumours. Another example was the "strawberry gall-bladder" which was first described by Sir Berkeley Moynihan, who pronounced it to be a dusting of the surface of the gall-bladder with gall-stone material. The small polypoid projections here seen were pendulous collections of foamy cells, gorged with cholesterin. The speaker thought that these might act as originators of the mulberry type of gall-stone, which was preponderatingly a cholesterin stone. Cholesteatomata of the choroid plexuses were not uncommonly found as incidents in a post-mortem examination. These little tumours presented the same structure as the allied formations found elsewhere, consisting of masses of foamy lipoid-containing cells. In the later stages of their existence the cells dissociate and free cholesterin was deposited.

Atheroma was a closely connected condition. Here a deposit of cholesterin was a constant feature of the early atheromatous plaques, and a like condition might be produced by feeding animals with cholesterin. All these conditions might be looked upon as examples of local deposits, determined by a general condition of hypercholesteræmia. In the morbid states now to be described the local deposits were not accompanied by any general metabolic change. "Myelin kidney" was an example of the latter type of disease. Here there was an extensive deposit of lipoid between the cortex and medulla of the kidney. In an early stage this substance was intracellular, and foamy cells were seen. The speaker regarded this condition as a special modification of subacute nephritis; in the early stages the lipoid could be seen in the renal epithelium and it was on disintegration of this that it was deposited in a free state. In panniculitis the same foamy cells were found as the result of a low-grade inflammation of the subcutaneous fat. The myeloid tumours of tendon sheaths often contained the same lipoid-filled cells, and it had been held by some that they were really xanthomata. The speaker pointed out that the true xanthomata of tendons were found in general xanthomatosis and were quite distinct from the myeloid tumour. His view was that the foamy cells occasionally seen in the latter represented a phase of degeneration in an endothelioma.

Dr. ARCHIBALD LEITCH read a paper on

Mule-Spinners' Cancer and Mineral Oils.

He pointed out that 20 per cent. of the cases of scrotal cancer occurring in this country were present in mule-spinners and that an additional 6 to 7 per cent. were in chimney-sweeps. No other occupation had an incidence of over 2 or 3 per cent. Certain mineral oils, shale-oil in particular, had the capacity for producing tumours in mice. Most lubricating oils contained a high percentage of petroleum oils which had also been found to produce the same result. The time taken to produce carcinoma by lubricating oil was greater than that taken by any other agent yet tried successfully for this purpose. The results varied with the different fractions employed, those distilling at a high temperature being more active than the more volatile fractions; this statement was also true of the more active shale oils, so it could be concluded that it was in these fractions that the active agent chiefly resided. With regard to the localisation to the scrotum, the speaker held that it might be due to the large sebaceous follicles there present, and thought that following a period of exertion and sweating material from the surface might be drawn into these follicles and act there. In chimney-sweep's cancer the active factor lay not in the carbon particles of the soot, but in a fraction which was soluble in sebaceous material, and with such a product carcinoma had actually been experimentally produced.

In the discussion which followed Dr. W. F. DEARDEN said that he had 30 years' experience of cotton mills. It was a curious thing that within the cotton trade itself knowledge of the disease was practically non-existent, largely because the spinners tended to conceal it, and hence the problem of prevention had scarcely yet been faced. There was no doubt that the men became saturated with oil from the cotton trousers worn when at work. The oil was not derived from the faller bar, as had been stated, for a boy was employed to keep this clean from oil, but was derived from the spindle bearings which sent off a fine spray of oil. The effect of the faller bar might be to press the oily trousers against the scrotum.

Dr. S. A. HENRY said that industrial epitheliomatous ulceration of the skin was a notifiable disease, but that epithelioma of the scrotum was not usually notified, probably on account of failure to recognise that the disease was an industrial one. The disease was one of very slow development; the earliest case he had found developed after 19 or 20 years' continuous employment in a mill. Change of occupation after a long period of spinning did not mean indemnity from the disease, as experimental work had shown in mouse tumours. He asked if Dr. Leitch could give any information as to the prevalence of this disease in America.

Reply.

In reply to a number of questions raised by different speakers, Dr. LEITCH said that cases of chimney-sweep's cancer were very few and he had not had an opportunity of demonstrating soot in relation to the sebaceous glands. Sebaceous material alone did not appear to have any carcinogenic qualities. With regard to scrotal cancer amongst cotton-spinners in the United States he had made careful inquiries, but had only succeeded in hearing of two cases. One possible explanation might be that the employees in that country did not spend as long a time at the same occupation as they did in this, where it was quite usual for cotton-spinners to pass their whole lives in the same trade. The location of cancer in the scrotum might be explicable upon the lines of its being a seat of election. In animals it was easy to produce epithelioma in one site, but more difficult in others.

Dr. J. E. MCCARTNEY read a paper on the

Criteria of Transmission and Cultivation of Encephalitis and Allied Viruses.

He pointed out the divergent results claimed by various workers with human encephalitis material. On the one hand, Strauss, Hirshfeld, and Loewe, in America, and Kling and Davide, in Sweden, obtained frequent positive results similar in type and not necessarily causing symptoms or death of their experimental animals, but nevertheless producing well-marked lesions in the animals' brains. Levaditi and his associates, in France, claimed positive results of a different nature, after a different incubation period, accompanied by symptoms in the animal and finally by its death. It had been noted by Bull that in certain normal rabbits lesions were found in the brain akin to those described as specific for the encephalitis virus, and at the suggestion of Flexner the speaker examined nearly 400 rabbits from the Rockefeller Institute with the object of ascertaining if lesions were present in normal animals, and in animals the subjects of other infections, of the same nature as those obtained by the workers with human encephalitis and what might be their prevalence. He found in all the different categories of animals examined that such lesions might be detected. These were of several types: (1) The perivascular infiltration with round cells, familiar to all workers at encephalitis; (2) similar submeningeal infiltrations; (3) sub-ependymal collections of the same nature; and (4) focal aggregations and general infiltrations of round cells, sometimes associated with areas of necrosis. On an average such lesions were detected in about 50 per cent. of all the animals examined. Cultural experiments in such cases had proved uniformly negative both by ordinary methods and by the Noguchi method. In certain experiments with accredited viruses of encephalitis and herpes cultural experiment had also proved negative, and it had been shown that the survival of the virus in Noguchi medium, which had been claimed as suitable for its cultivation, was of shorter duration than in ordinary broth.

Prof. **Browning** felicitated Dr. McCartney on having carried out a very laborious piece of work of an especially praiseworthy variety, since its results were negative. He had been watching work of a similar nature upon disseminated sclerosis and believed that the pitfalls which had been pointed out had been successfully avoided.

Dr. **Dible** said that what Dr. McCartney had done was to carry out the controls which other workers had failed to provide for. It did not, however, follow that his findings were universally applicable. The speaker had examined the brains of many rabbits, in Manchester, in the course of attempts to transmit human encephalitis and had not found these lesions. The explanation probably was simply that they were dependent upon an infection, which might be present in some areas and in some breeding houses but not in others. He thought that it was time to call in question much of the work that had been put forward with positive findings in this field. A large amount of published work had been built up and its foundations were very uncertain. For the last four or five years he had been trying to transmit human encephalitis to rabbits, using many varieties of material—fresh brain, glycerinated brain, and cerebro-spinal fluids—and essaying inoculations by all the routes for which positive results were claimed, and to his sorrow he had been completely unable to obtain any positive results. There was a tendency, he thought, to interpret such lesions as perivascular infiltrations in too narrow a sense. They were appearances due to anatomical and physiological conditions in the brain, which determined what the picture would be in response to infection; they might be occasioned by many infections—this was a commonplace—and they were certainly not to be looked upon as specific of any single infection.

Dr. J. **Cruickshank** read a paper upon

A Study of B. Acidophilus *in Human Fæces.*

No one, he said, could fail to be struck by the number of Gram-positive bacilli seen in films of stools and by their absence in ordinary cultures. These organisms were acid-resisting, and it was easy to cultivate them by thickly implanting fæces into broth to which 1 per cent. of acetic acid was added. After incubation, plating resulted in an abundant growth of these bacilli along with certain cocci. *B. coli*, which seemed to exert a definite inhibitory effect on the growth of these organisms, was killed off. The acid-resisting organisms of this type constituted the aciduric group, to which *B. bifidus* was closely allied. Forty-four strains had been examined and an attempt made to group them by sugar reactions, but this was not satisfactory on account of the multitude of types which resulted. Agglutination had been no more successful, but types absolutely identical by sugar reactions appeared also identical with regard to agglutination. Many different types might occur in the same stool. There was much confusion over the whole group and he did not think that any of the members showed a real preference for anaerobic conditions.

Dr. R. P. **Smith** read a paper on the

Isolation and Implantation of B. Acidophilus.

He had endeavoured to implant pure isolated strains of *B. acidophilus* in the intestine in typhoid carriers for therapeutic purposes. This was successful as long as feeding with the organism was maintained, but when this was stopped the bacilli quickly disappeared. Feeding with lactose prolonged the period of persistence of the organism. Attempts were also made to implant *B. lactis aerogenes;* these failed, except in a case in which the feeding was associated with vaccination with this organism. As a therapeutic measure such implantation relieved chronic constipation, but did not affect the presence of *B. typhosus* in carriers.

Dr. R. **Row** read a paper on the Experimental Transmission of *Leishmania tropica* to Mice by Feeding. Only certain regions of the intestine showed any lesions as a result of this, these appearing mainly in the lymphoid follicles of the jejuno-duodenal junction. The transmission of the disease by biting insects was at present discredited, and from the experiments discussed he did not draw any positive inferences in favour of an intestinal origin for the condition.

SECTION OF DISEASES OF CHILDREN.

Wednesday, July 23rd.

This section met on two days, Dr. **Leonard Findlay**, the President, being in the chair. At the first session Dr. A. F. **Tredgold** (London) opened a discussion on

Prevention of Mental Deficiency.

He confined his remarks to mental deficiency as defined by the Mental Deficiency Act of 1913. He said that mental defectives could be divided broadly into two groups, primary and secondary. The essential cause of primary amentia was a diminished developmental potentiality of the cerebral neuroblasts, which was germinal in origin and was inherited or transmitted. Two chief views were held as to the nature of the germ change: (1) That the change in the germ plasma was "defect mutation," which was inherited as a Mendelian recessive; (2) that the change consisted in a form of germ devitalisation, the result of injurious factors of the environment (e.g., lead, mercury, tuberculosis) acting upon the germ cells or impairing the growth potentiality of the neuronic determinant. This impairment was manifested in varying degrees—defective function (hysteria, epilepsy, mental instability), defective durability (chronic forms of insanity, dementia præcox, pre-senile dementia), and defective structure (varying degrees of mental defect or subnormality). An additional embarrassment due to birth injury, antenatal or postnatal disease might bring about mental defect where the innate tendency to impairment of development was only slight. In his opinion, the latter view was the better one and was most in harmony with our present pathological, clinical, and genealogical knowledge. It should be noted that it was not the mental defect but the impairment of developmental potentiality or germ neuronic determinant—i.e., the neuropathic diathesis—which was inherited or transmitted.

In speaking of prevention, he said it was often assumed that to prevent mental defect it was only necessary to sterilise or segregate mental defectives. This was a mistake, for, whichever view was adopted, the Mendelian or the theory of germ impairment, segregation, or sterilisation would be attended with only limited preventive results. On the Mendelian view Punnett had shown that, assuming an initial proportion of one mentally defective per 100 population, these methods would have to be continued for 22 generations to reduce the proportion to 1 per 1000. If the view of germ devitalisation was adopted it was clear that the sterilisation or segregation of certifiable defectives could only be attended with limited results. These methods would only prevent those cases which are the offspring of mentally defective parents, and the proportion of these is relatively small. To produce any appreciable preventive result it would be necessary to sterilise all those who suffered from the neuropathic diathesis—an impracticable and impossible proceeding. As a policy segregation was better than sterilisation; mentally defectives were antisocial and therefore must be segregated for their own sakes, sterilisation being then unnecessary. If sterilisation were relied upon it would mean the setting free of many people who should be under control. Birth-control would certainly not prevent mental deficiency; on the contrary, there was every reason to think that it would increase the number of cases. What was needed at the present time was not the indiscriminate advocacy of birth-control, but the encouragement of the multiplication of the biologically sound and fit, and the discouragement of the unsound and unfit.

Raising the question of the possibility of prevention of germ deterioration, he said that as long as it was assumed that this arose by mere chance or from unknown causes, nothing could be done, but if the assumption that it was due to faults of the environment be correct, then it came within the sphere of practical preventive medicine. Secondary amentia differed from primary amentia in that the germ plasm was normal and there was no morbid heredity: it was produced by adverse causes of environment acting directly upon developing embryo or young child; more antenatal research was essential. In cases due to vascular brain lesions the lesions were generally produced during birth and therefore called for improvement in methods of delivery. He asked whether operation would be possible in these cases. More research was also necessary in Mongolism and into the bacteriology and treatment of these cases resulting from toxic or inflammatory brain lesions. In cases due to syphilis treatment of the child was of no value; the parents of the child should be tested for evidence of the disease and treatment applied to them.

Dr. ERIC PRITCHARD (London) said that if the germ plasm could be injured by noxious influences—e.g., lead, mercury, &c.—and the influence continued through several generations, it was only logical to suppose that when these influences ceased to damage the germ plasm through many generations these inborn traits would breed out. The feeding experiments of Mendel, McCollum, and others showed that food could influence germ-plasm growth and reproduction, and it was therefore logical to assume that the nerve elements in the germ plasm would be affected to a greater degree. Food accessory factors, particularly vitamin-B starvation, might be one of the most potent causes of injury to the germ plasm in successive generations. With regard to Mongolism, he would draw attention to a recent paper in the *American Journal of Diseases of Children*, in which it was suggested that the condition was a primary one. The author investigated the case of Mongolism in 18 pairs of twins: in two cases only were both twins Mongols and these were homologous twins; all the other were heterologous twins. Under these circumstances, it was impossible for the condition to be a secondary one. Mongolism could not be due to germinal influences, for it is rarely seen in families and rarely in more than one child of the same mother. He wished to ask Dr. Tredgold, therefore, if he was convinced that Mongolism was secondary.

Dr. ROBERT HUTCHISON (London), speaking purely from his clinical experience of 150 private cases, said that the classification of mental deficiency into primary and secondary forms was a purely arbitrary one. Secondary forms simply meant those in which the cause was known, and primary those in which it was unknown. It was absurd, therefore, to classify Mongolism as a secondary form, because its cause was unknown. He classified his cases purely on clinical grounds, and of the 150 cases Mongols formed 35 per cent., epilepsy 6 per cent., cretins 6 per cent., and primary amentia 45 per cent. Attention therefore should be concentrated on the prevention of primary amentia and Mongolism. There was no evidence that primary amentia was hereditary and transmissible. Every one of his audience, he said, had a neuropathic inheritance, and indeed it was the only one worth having. With regard to the factors producing a damaged germ plasm, Dr. Tredgold dragged in endocrine disturbances and hypothetical toxins, while Dr. Pritchard emphasised the vitamins. These he regarded as the resources of the intellectually bankrupt: if they had nothing better to bring forward then there was no evidence of the action of toxin. Neither of the two preceding speakers had made any reference to the fact that these children were usually the first-born children: it would appear that nature made a botch of it at the first pregnancy, and after that appeared to be more successful. If these cases were to be prevented the only logical treatment appeared to be that of slaying all the first-born! Another point also not mentioned by these speakers was that the mothers of Mongols were almost always somewhat old—in 75 per cent. of his cases the mothers were over 35 years of age. Therefore, on that ground alone the only practical prevention of Mongolism would be to prevent all women over 35 having children. With regard to the other forms of mental defect, head injury cases might be prevented by early version, Cæsarean section, and appropriate measures, but they formed only 10 per cent. of mental deficiency. The very small part played by syphilis in mental deficiency had been well shown by John Thomson's statistics. He believed that mental deficiency was no more inherited than hare-lip or cleft-palate: it arose as a fortuitous variation. Every generation produced its crop of mentally deficient as it produced its great men; and in conclusion he quoted Sairey Gamp—"We were born in a wale and must take the consequences."

Dr. W. A. POTTS (Birmingham) said he could not agree with Dr. Hutchison that the inheritance of mental deficiency was disproved; how was it that if two mentally deficient people married all the offspring were mentally defective? He agreed that segregation alone would require a very long time to obtain good results, but if other factors, antenatal and natal, also received attention practical results would be obtained. As special causes in the production of mental deficiency he instanced the effect of toxic conditions—e.g., pyorrhœa during pregnancy—which were most dangerous in the first six weeks of pregnancy. Too rapidly repeated pregnancies also affected the children. An improvement in obstetric practice would lessen the number of cases of mental deficiency.

Dr. LANGDON-DOWN (London) was in substantial agreement with the arguments and conclusions of Dr. Tredgold. He agreed with him in rejecting compulsory sterilisation as a necessary or wise method for the prevention of mental deficiency. And to be effective at all, it would have to be compulsory. Segregation produced the same results as sterilisation, and fulfilled also the other conditions of the problem. To decide what class of case should be sterilised was a problem bristling with difficulties.

Dr. R. M. MARSHALL (Manchester) agreed that the neuropathic diathesis was not inherited as a Mendelian recessive, but he could not go all the way with Dr. Tredgold when he suggested that the diathesis arose from a devitalism of the germ plasm which produced certain nervous disorders and reached a culmination in amentia. This would imply that the neuropathic diathesis was a progressive condition, originating as a functional neurosis and ending as mental deficiency, and was simply a statement in modern pathological terms of the old doctrine of family degeneration. He thought that Dr. Tredgold's paper helped to establish certain points in the prevention of amentia, and that he placed the proper emphasis on sterilisation and segregation. Sterilisation was not calculated to get at the morbid process responsible for the condition, and segregation, if adopted early in life, prevented the reinforcement of certain types of society which were a burden to the ratepayer.

Dr. BERNARD MYERS (London) supported Dr. Hutchison's classification as a practical clinical one, and emphasised the importance of looking after the pregnant mother, and particularly the prevention of infectious diseases.

Dr. W. CROFTON (Dublin) said that everyone who had studied the influence of environment on the morphology of micro-organisms was convinced of the importance of environment, and he considered it was the first duty of the Government to provide minimum standards of wage, food, and housing.

Dr. A. E. NAISH (Sheffield) thought that Dr. Hutchison's view against heredity was due to the fact that he was dealing with private cases among which sporadic cases occur more than in any other class. With regard to Mendelism, he thought they should adopt the theory of non-proven rather than deny it. If Dr. Tredgold's theory of pathological change in the germ plasm—showing itself in the least degree as hysteria, in a more severe degree as dementia præcox, and culminating in amentia—were true, one would expect a large number of cases showing a mild degree of mental defect to develop into dementia præcox as they grew older.

Dr. C. F. LAPAGE (Manchester) said that there was no distinct gap between mental deficiency and lower grades of those children who were not actually certifiable. He held it was not hereditary change but rather some alteration in germ cell or in embryo. The effect of stock was undoubted in many cases.

Dr. H. B. BRACKENBURY (London) thought that there was a tendency in the discussion to deny that there was any such thing as mental deficiency. He held there was an absolute distinction between mental deficiency and backwardness or dullness, if they could be diagnosed, although he regarded the diagnosis as difficult. If our knowledge were complete we could diagnose between the two conditions.

The PRESIDENT said that the subject was chosen for discussion because the lay press often wrote as if the presence of mental deficiency was an indictment of the medical profession, and as if the profession knew how to prevent it but did not. The discussion was arranged so that a definite opinion could be given to the public, but he was afraid that that object had not been achieved. It could not be doubted that heredity played a big part in mental supply just as it did in stature, eye colour, and other traits, but mental deficiency was different. There was no concrete opinion regarding the cause. He thought congenital and acquired were better terms than primary and secondary; the problem that presented itself was the prevention of the congenital defect, since the prevention of the secondary defect was only a question of better medicine. Mental deficiency was common in better classes, and in them he had not been able to find a family history pointing to heredity. He would not be astonished if the better classes had not a larger number of mental defectives than the poorer classes, and this took the causation right away from the problems of housing or feeding. It had been suggested that with better obstetrics there would be less mental deficiency, but it was a curious fact that the more training there was in obstetrics, the more accidents there were at birth. It tempted the doctor to do more than he otherwise would, and tended towards hurry. We were spending a large amount of money on treatment of mental deficiency, and he would ask Dr. Tredgold if it were worth while. What percentage of mental defectives could support themselves?

Reply.

Dr. TREDGOLD, in reply, said that he did not know whether Mongolism was primary or secondary, but he thought environment acting on the child did have an effect; the cause was, however, unknown. Dr. Hutchison swept aside all knowledge, heredity, science, and reduced the question to one of clinical experience and of chance; but the more we knew of mental deficiency the more we saw that, although as yet unknown, there was a cause for it. There was clear experimental evidence that adverse circumstances did affect the germ plasm and that as a result the embryo was affected. He was quite definite that there were thousands of families without a neuropathic inheritance, and that it was in the unsound families that mental defectives were found. Dr. Marshall was probably thinking of school-children found in mentally defective schools—i.e., morons. If so, he entirely agreed with him, because there was a clear difference between morons and mental defectives. The moron is the lowest grade of normal, the mentally defective is a definite pathological condition. He also agreed with the President in thinking that the social class of the parents made no difference to the occurrence of mental deficiency, and therefore it was not due to housing or food. In answer to the President's question whether it was worth while spending money on the treatment of mental deficiency, he would ask what was the alternative? It was to leave these mentally defectives at large to work their will on society now and on posterity in the future. Therefore, we must segregate them, and if we must do this why not do the best we can for them? There were thousands of cases earning enough to pay for their keep.

THURSDAY, JULY 24TH.

On the second day Dr. CLIVE RIVIERE (London) opened a discussion on

Pulmonary Tuberculosis in Childhood.

He said that the original title advertised for the discussion was pulmonary tuberculosis in childhood, but that in the official handbook this had been changed to pulmonary tuberculosis in children of the school age and that his own remarks would be on that point, and he would deal with the clinical aspect of the question. He hoped that other speakers would say which part of the subject they were speaking about. For the ages 5 to 15 years the Registrar-General's report showed that the number of deaths attributable to tuberculosis was only 3 per cent. of the deaths at all ages. This low mortality admitted of two possible explanations—that there was little infection at these ages, or that children of the school age had a high immunity. He gave statistics to prove that infection at these ages was quite common, and also post-mortem figures proving that structural lesions were discoverable during these early years. The conclusion was therefore an obvious one, that there must be a notable immunity during this period of life. Among such material, infective but resistant, there must surely be in addition to a few deaths, numerous cases of disease running a more benign course and ending in recovery. How did these cases show themselves clinically and where were they found? He did not think they were found in hospitals, but they were found in tuberculosis dispensaries and in the school medical service. The tuberculous child was a type that could be recognised. There was a history of frequent coughs and colds, attacks of unexplained fever, loss of weight, anorexia, and asthenia. How were these cases to be detected? The stethoscope was useless in the diagnosis of hilus tuberculosis; it was only useful in detecting those uncommon cases of apical phthisis in children and the late stages of hilus tuberculosis, both of which varieties of the disease possessed a bad prognosis. There were, however, certain characteristic areas of dullness, the most characteristic being the right paravertebral dullness. This was as characteristic of hilus tuberculosis as apical dullness was of apical phthisis. The diagnosis of hilus tuberculosis then depended on the right interpretation of the symptoms, the finding of right paravertebral dullness by percussion and on well-interpreted X ray photographs, but not on the stethoscope. Unfortunately, the radiograph of later childhood was marred by shadows of past experience, but in earlier childhood a well-interpreted X ray was very helpful. He believed that the infection of the lung was a backward lymphatic spread from the hilus.

For purposes of discussion he would suggest some of the problems which hung around this tuberculous or sub-tuberculous school-child. First, his very existence seemed to be ignored in some quarters, and he hoped this discussion would help to establish it. Next, given his existence, came the detection and diagnosis of his disease, and following that the peculiar characteristics of pulmonary tuberculosis in childhood, and the points wherein it differed both clinically and pathologically from apical phthisis of adult type. These he had tried to outline, and they presented an interesting problem. Further, there remained the question of prognosis in the individual case, none the less difficult because the majority recovered readily. In addition, there was the question of what was to be done with the sub-tuberculous child from the administrative point of view, both in the interests of the child himself and of the community. Finally, there remained the very important and interesting question of what eventually became of him, particularly on his emergence into adult life. Did he recruit the ranks of phthisis in the adult, or was he, as some believed, peculiarly immune to further tuberculous disease? Or were there, perhaps, cases which were protected by their childhood disease, and others in which it had obtained so firm a foothold as again to become active in the guise of a hilus tuberculosis of adult life? These among many he would suggest as suitable problems for discussion within the limits of the subject-matter.

Radiological Aspect of Pulmonary Tuberculosis.

Dr. **CAMPBELL SUTTIE** (Glasgow) spoke on the radiological aspect of pulmonary tuberculosis and dealt particularly with children under 5 years of age. He said that in the experience of the radiological department this was a comparatively uncommon and invariably fatal disease. The majority of those infected died in hospital and the disease usually lasted but a few months. He gave a detailed description of the technique employed, and said the radiogram gave accurate pictures of small peripheral and larger central lesions which had reached the stage of consolidation or cavitation before the corresponding physical signs could be detected. Progression of the disease was evidenced by the increasing opacity of the abnormal shadows, their spread in extent, their edges becoming less distinct owing to surrounding consolidation, the signs of cavitation in their centres, and by the appearance of abnormal shadows in the other lung.

From the radiographic standpoint there were four types of tuberculous infection: (1) Miliary tuberculosis; (2) broncho-pneumonic tuberculosis (Types A, B, and C); (3) hilus tuberculosis; (4) chronic phthisis (adult type). In miliary tuberculosis the chest was normal in contour and the X ray findings were negative. The hilum shadows were not more prominent than those found in supposedly healthy children, and yet at post-mortem examination there might be miliary tuberculosis present throughout the lungs with enlarged mediastinal glands. He did not think that tuberculous glands showed radiographically unless they had passed the stage of congestion or enlargement and had become caseous or calcareous. In broncho-pneumonic tuberculosis (Type A) the hilus shadows were almost invariably increased, and the whole field of both lungs dotted with rounded, sharply-defined areas of opacity, almost all of the same size and equally distributed. The size of each of these shadows varied with each case, from about 1 mm. to 3 mm. in diameter. They did not seem to coalesce until the individual lesion exceeded 3 mm., thereafter over large areas of lung dense shadows were produced, followed immediately by appearances indicative of cavitation. Acute broncho-pneumonic phthisis (Type B) was rare. Radiologically it was indistinguishable from a broncho-pneumonia which was breaking down, except that both lungs were not usually infected. Large cavities might be formed and spread the infection to the other lung. In Type C there was occasionally and usually in the lower lobes a caseous area which might have been the focus of the miliary spread. Hilus tuberculosis was more uncommon, and began as an increase in the size and opacity of the hilus shadow. Occasionally both were involved, but one increased at a much more rapid rate. Eventually the opacity might reach the lateral chest wall, but before this occurred an irregular area in the centre showed increased translucency, and within a short time a large irregularly-shaped cavity was seen. In tuberculosis of the lung with broncho-pneumonic or hilus type in infancy a unilateral chest infection had not yet been seen. The evidence of chronic tuberculosis in childhood was seen first as an increase in size and opacity of the hilus shadow. This opacity finally extended to the apex of the affected side as an elongated branching shadow showing at intervals along its course circular opacities with fairly well-marked outlines. These shadow areas were not discrete, but communicated with each other, and at the apex or below it there was an area of consolidation with at a later stage cavity formation.

In diagnosis he emphasised the difficulty of the apparently normal variations in extent and density of hilus shadows and the shadows caused by the bronchi and their vessels. Also the difficulty in diagnosing other bacteriological shadows such as the increasing hilus branching shadows, which may persist for many years after measles, whooping-cough, and influenza. The lung picture might be due to other processes, such as unresolved pneumonia. He stated in conclusion that he believed the broncho-pneumonic Type A to be the most common form of pulmonary tuberculosis in children detectable radiologically, and that it produced the radiogram on which alone a diagnosis can be made with reasonable certainty.

Dr. **LAPAGE** said he believed that children of the school age showed a high immunity to pulmonary tuberculosis. Hilus tuberculosis at the school age, particularly the mild form, was difficult to diagnose, and in diagnosing it he would lay stress on the following points: (1) The importance of the toxic state—e.g., headache, pallor, debility, after the elimination of all other possible toxic causes. (2) The appearance of the child on examination, there was a loss of tone of the whole system, the child "looked shabby," the skin was dry and dirty, there was a growth of downy hair on the back, a loss of tone of ligaments, flat-foot, and exercise tolerance was poor. Prof. Lorrain Smith stated that there were pathological changes in the muscle. (3) A history of exposure to infection. He believed that the infection was via the bronchial mucous membrane, to the glands, and later retrograde infection of the lung. (4) On percussion, paravertebral dullness might be present in healed or active tuberculosis. On auscultation he thought D'Espine's sign was useful. (5) An X ray examination; the interpretation of this was, however, difficult. (6) The reaction to treatment—if a child improved greatly on rest, climate, and dietetic treatment, the diagnosis was confirmed. He made a plea for more schools for children for the lengthy treatment of mild cases of hilus tuberculosis.

Dr. **C. W. VINING** (Leeds) said it was important to distinguish between tuberculous infection and tuberculous disease. Impaired health was too commonly put down to tuberculosis. Localised tuberculosis did not affect the health very greatly; if ill-health were present it was due to toxæmia, which meant a severe and spreading lesion, and the majority of such cases died. He would like to know what percentage of school-children in cities showed the signs Dr. Riviere had described; he thought that post-mortem statistics from a general hospital were more likely to express the disease incidence in the community than statistics obtained from children's hospitals. He therefore had examined the post-mortem records at the Leeds Infirmary of cases from 5 to 14 years of age. Of 103 cases in which death was due to accident or burns, tuberculous lesions were present in 14 per cent., and only four cases showed intra-thoracic lesions. He did not understand how enlarged bronchial glands could produce paravertebral dullness. Dr. Riviere had said that this was due to alteration in the surrounding lung, but it was difficult to see how this was brought about, because the root of the lung was tucked away deeply in the chest and covered over by a mass of lung tissue.

Dr. **CHARLES MACNEIL** (Edinburgh) said that the type of child spoken of by Dr. Riviere was the common type of latent tuberculous disease in children of the school age. The diagnosis was important because these cases were amenable to treatment. In his opinion children of the school age were diagnosed as suffering from chronic tuberculosis in far too large numbers. Raising the question whether it was possible to diagnose mediastinal glandular tuberculosis, he said that if Dr. Riviere's claim for right paravertebral dullness were sound it was an important contribution, but it was the last of a series of signs that had been offered, such as Eustace Smith's murmur, D'Espine's sign, parasternal dullness, all of which were now largely discredited. He was entirely unconvinced that paravertebral dullness was any better than these other signs. The objections he had to it were that it was not a true dullness, it was only impaired resonance, and that normally there was along the vertebral border an area of impaired resonance. There was no local sign that was generally available and the diagnosis was very difficult, indeed, it was often rather a probability than a certainty, but if a child gave a positive von Pirquet's reaction and did not show any evidence of pulmonary or other disease, but had signs of general ill-health, it could be presumed that the child was suffering from tuberculous bronchial glands.

Dr. F. G. **CHANDLER** (London) said that pulmonary tuberculosis did occur in infancy and childhood, and that mediastinal glandular tuberculosis was common. At post-mortem there was frequently evidence of old tuberculosis in the mediastinal glands and therefore there must have been disease earlier in life. The absence of mortality between the age of 2 and 14 did not imply non-infection. Was it possible that tuberculosis destroyed the most susceptible before the age of 2 and then dealt gradually with the rest? Marked symptoms of tuberculous disease were not infrequently found at 15 years, therefore the disease must have been present before that time. There were many slight warnings of this tuberculous state which had been well defined by Riviere as sub-tuberculous, but it must not be thought that every case of malnutrition in childhood was due to tuberculosis. He stressed the importance in diagnosis of a barking, dry, paroxysmal cough at night, failure to gain weight, toxæmia as described by Dr. Lapage, paravertebral dullness, diminution of Krönig's bands, and the importance of sputum examination. If it were not possible to obtain sputum the fæces should be examined. In the absence of uninfected food, the findings of tubercle bacilli in the fæces was diagnostic of pulmonary tuberculosis. The X rays, unfortunately, gave the least help in the diagnosis of those cases where help was most required. As to prevention there should be avoidance of infection, a pure milk-supply, early diagnosis, and more frequent routine examination than were undertaken to-day.

Dr. W. B. **CROFTON** (Dublin) said that 25 per cent. of all cows supplying milk to London were tuberculous, therefore practically all the milk in London could be regarded as tuberculous. He stressed the difficulty of diagnosis of pulmonary tuberculosis in cases where no tubercle bacilli were found in the sputum, and also the importance of the subcutaneous tuberculin test as a help in diagnosis. His experience with his own antigen was that he had never known a case which developed tuberculosis, if after three or four days the reaction was negative.

Dr. J. A. **WATT** (Derby), speaking of children of the school age, said that he agreed with Dr. Riviere that hilus type of infection was the common form of the disease, and also that right paravertebral dullness was present in these cases. He thought D'Espine's sign was of great value and also the examination of the sputum, but the latter must be done by concentration methods. 45 per cent. of hilus cases showed tubercle bacilli by these methods and the mortality after four years of this group of cases was small, whereas of 60 cases of the adult type of infection which developed from 10 years onwards, 80 per cent. had died in four years. As to the future of cases of the hilus type, he believed that it developed into adult tuberculosis in after life, and he thought public money would be better spent in treating these children than in treating adult tuberculosis.

Dr. **ERIC PRITCHARD** thought that the diagnosis of this form of tuberculosis required simple means and that the refinements of percussion as suggested by Dr. Riviere were too great. He had had great success with subcutaneous test and did not know why it was not more used. He found no danger in it, but it must be remembered there was a difference between the bovine and human type of infection. A focal reaction was of great diagnostic importance. If there was a general reaction only, then the child must receive specific prophylactic treatment. Malnutrition must not be regarded as an essential point in diagnosis, since tuberculosis occurred in quite well-nourished children. He had used tuberculin prophylactically with great success, and of 40 cases in infants exposed to infection, who gave a focal or general reaction and to whom he had given a six months' course of tuberculin, all were now alive. This disproved Hamburger's and Monti's statement that 90 per cent. of all infants infected with tuberculosis died.

The **PRESIDENT** said that the discussion had been comprehensive, but the subject chosen for discussion was not tuberculosis in children but pulmonary tuberculosis, and he wished speakers had stated more definitely the type of case they were discussing. What we wanted to know was how frequently we met with pulmonary tuberculosis. Physicians in children's hospitals saw every form of case and therefore the children's hospital could be taken as supplying evidence as to the frequency of the disease. In Glasgow tuberculosis of the lungs during school age was rare. When it was diagnosed death soon occurred. If cases of mediastinal gland tuberculosis were classed as pulmonary tuberculosis, then, of course, it was much commoner. Tuberculous mediastinal glands was one of the most difficult diseases to diagnose. Evidence of improvement when country life was substituted for town life was not evidence that tubercle was present. It was questionable whether with all precautions it was possible to get tubercle-free milk; sterilisation of milk was therefore essential.

Replies.

Dr. **SUTTIE**, in replying, said that his remarks were based on a large number of radiological examinations. About 1000 radiograms of chests were taken every year. He could not say that an X ray examination was any help in the diagnosis of enlarged mediastinal glands unless these were very large or calcareous. As a matter of fact, all forms of pulmonary tuberculosis except the broncho-pneumonic type could be simulated by other diseases.

Dr. **RIVIERE**, in replying, said that, in answer to Dr. Lapage, symptoms could never be anything more than mere indications for examination, although it was necessary to rely on them for evidence of activity of the disease. He thought Dr. Vining's figures substantiated his own view that many cases ought to be found in practice. He agreed that there was no sufficient explanation of paravertebral dullness, but thought it was probably due to enlargement of the bifurcation glands pressing on the right pulmonary artery and resulting in under-expansion of the right lung. He had not often been able to find tubercle bacilli in the sputum, and in answer to Dr. Crofton's remarks about tuberculin, he thought that most people agreed that a mere general reaction was not of great value, although a focal reaction was important, but he had not used this method in children. He did not agree with Dr. Watt that hilus tuberculosis of children became the adult type of tubercle, but he suggested that it might give rise to those deep cases of tuberculosis seen in adults.

In answer to the President, he said he himself had found these cases did not go to children's hospitals, but were sorted out in schools and sent to dispensaries for tuberculosis or to chest hospitals, but possibly in Glasgow conditions were different.

THE annual meeting of the Medical Sickness, Annuity and Life Assurance Society will be held at Lincoln House, 300, High Holborn, London, W.C. 1, on Monday, Oct. 6th, at 4 P.M.

Special Articles.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Pensions of Poor-law Medical Officers.

THE Local Government Bill, introduced to the Dail last session, proposed to repeal all existing enactments dealing with the superannuation rights of Poor-law medical officers, and to substitute conditions much less favourable. Representations made to the Minister have convinced him of the injustice of this proposal in so far as it affected existing officers, and he has decided to propose amendments to protect their interests. In reply to a query as to his intentions from the Secretary of the Irish Medical Association, an official letter from the Ministry states: "The Minister desires me to state that he has decided to introduce into this Bill amending clauses which will fully preserve all the present rights to superannuations or gratuities on retirement of officers holding office at the date of the Bill passing into law."

A manifest injustice to existing officers is to be avoided, but the profession will not be satisfied that worse conditions as regards pension should be applied to future officers than are in force at present. The public services of Ireland need to be rendered more attractive rather than less so if the medical system is to be efficient.

The Position of the Medical Profession in the Free State.

Dr. Hennessy, Medical Secretary of the Irish Medical Committee, addressing a largely attended joint meeting of the medical practitioners of the counties of Wicklow and Wexford which was held recently, discussed the legislative proposals of the Government and the adverse conditions likely to occur if the profession were not immediately organised on a thoroughly satisfactory basis. The following pledge, already adopted by the counties of Kildare and Meath, was approved by the meeting and was signed by all the members present.

> "We, the undersigned medical practitioners, hereby bind ourselves by any action involving the resignation of our offices, or any other course which may be deemed necessary to be adopted by the Irish Medical Committee, as representing the Irish medical profession, towards securing satisfactory conditions of medical service in Ireland."

Medical Officers and Political Activity.

In several instances in the last year the Minister for Local Government refused to give his sanction to the appointment as dispensary medical officers of medical men supposed to have been associated with the military activities of the Republican party. It would appear that the Government no longer finds it necessary to take such action. In the case of Dr. Tubridy, of Connemara, whose appointment the Minister refused to sanction some months ago, sanction has now been given. In conveying this decision the Minister remarks: "The Minister is far from desirous of extracting humiliating undertakings from participants in the Irregular operations, although he does not minimise their disastrous consequences. Many of those who participated were misguided, and found themselves committed deliberately without adequate opportunity of considering their position. It appears that the Board of Health are assured from personal knowledge that in the case of Dr. Tubridy no guarantees are necessary from him as to future conformity. In all the circumstances, and in deference to the wishes of the Board of Health, the Minister will not further withhold his sanction to the appointment. In coming to this decision he has taken into account that Dr. Tubridy is a fluent Irish speaker, and that the district concerned is largely composed of native Irish speakers. He has also been favourably impressed by reports of his medical staff as to the devoted service rendered by Dr. Tubridy during former epidemics of fever."

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Wagner-Jauregg Treatment of General Paralysis of the Insane.

THE treatment of general paralysis by injecting the plasmodium of malaria, as devised by Prof. Wagner-Jauregg, of Vienna, has been tried in Germany also. In a report from the Clinic for Psychical Diseases which appeared in a recent issue of the *Zeitschrift für Psychiatrie*, Dr. Jossmann states that the method was tried in 100 cases of general paralysis. After an injection of 2 c.cm. of malarial blood, malaria developed in the patients under treatment in the form of quotidian fever, but was stopped after 12 attacks by the administration of quinine. As a rule, the patients passed through the fever without severe injury to their health; in several cases with cardiac weakness, however, the outcome was fatal. All stages of paralysis were treated by the method, and the result was that in 21 cases the patients were enabled to begin working again, although slight traces of paralysis were still present. In 28 cases the patients were able to resume work to a limited extent, the paralytic symptoms having undergone a considerable amelioration. In 39 cases no improvement worth mentioning was noticeable, and 12 cases died during or in consequence of the treatment. Even in the improved cases slight disturbances of speech and irregularity of the pupils remained. The intellect did not entirely return to normal, and a lack of insight into the state of illness remained. Dr. Jossmann comes to the conclusion that, although it is still too soon for a final judgment to be passed, it has nevertheless been ascertained that during the 18 months in which the Wagner-Jauregg method has been available, improvement has taken place in about 50 per cent. of the cases, especially in the early stages of the disease.

Prophylaxis in Goitre.

As in other mountain districts, goitre is endemic in Upper Bavaria, and similar prophylactic measures to those taken by the Swiss Government to combat this disease have been adopted. They consist principally in the use of iodine-salt for household purposes, which is sold everywhere instead of the ordinary kitchen salt. The salt, termed in Bavaria "Vollsalz," contains 0·5 g. iodine to each 100 kg. of salt, so that an adult person, taking on an average 20 g. of salt a day, receives about 0·07 g. of iodine, a quantity which is quite harmless. Dr. Eggenberger, surgeon to the cantonal hospital of Herisau, Appenzell, Switzerland, addressing the Munich Medical Society, gave a report on the results obtained by the use of iodine-salt. He stated that since the introduction of "Vollsalz" the annual number of operations for goitre in the hospital of Herisau had decreased from 40 to 11. Goitre in school-children had been reduced; infants whose mothers consumed "Vollsalz" did not show hyperplasia of the thyroid gland, a condition which formerly was present in about 50 per cent. of new-born children. He expressed the hope that by a permanent use of "Vollsalz" the incidence of goitre would be reduced to nil within ten years.

New Regulations for the State Examination in Medicine.

The existing regulations for the State examination in medicine have been modified, although its main scope has not been altered. For financial reasons it has not been possible to make the time of study longer than five years, in spite of the enormous pressure on the students' time involved by the lectures and clinical training in the different branches of the medical curriculum. The first two student years are devoted to chemistry, physics, botany, zoology, anatomy, and physiology, and after that time the preliminary examination in those branches is set. The following three years are given up to the theoretical and practical study of clinical medicine. The regulations provide new compulsory additional lectures on hygiene, orthopædics, and forensic medicine. The State examination will include 14 sections—namely, pathology and post-mortem examination. topographical anatomy, pharmacy, internal medicine, surgery, obstetrics and women's diseases, ophthalmology, diseases of the ears, the pharynx, and the nose, children's diseases, diseases of the skin, venereal diseases, psychiatry, hygiene, and forensic medicine. If a candidate fails in passing the examination at the first attempt, he may re-enter for it only once. The practical year subsequent to the State examination has been retained under the regulations; during the practical year the candidate must prove that he is able to give a professional opinion in forensic cases.

The Anti-Opium Law.

The German Parliament has recently passed a Bill dealing with the import, the export, and the sale of opium in accordance with the international conventions on that subject. According to the provisions of the Bill, raw and refined opium (morphine, heroin, &c.) may only be imported by chemical works and wholesale dealers who do not sell their products to the individual consumer; this special licence may be granted only to persons of good conduct and to recognised scientific institutions. From a medical point of view the principal feature of the law is that medical prescriptions containing opium may not be given back to patients, but are to be retained in the pharmacy; they must be produced on request of the district medical officer of health. In this way it will become difficult, if not impossible, for people who indulge in the morphia habit to procure morphine in several pharmacies by one single written prescription. The export of opium to foreign countries is permitted only when the Government in question has given its agreement, and this agreement is produced to the competent German authority. The import and export of opium for smoking purposes is strictly prohibited in accordance with the international conventions: offenders against this and the other provisions of the law may be punished with imprisonment not exceeding three years, and a fine.

The Society for Sports.

At the inaugural meeting of the newly founded Society for Sports (vide THE LANCET, July 5th, 1924, p. 40) which I mentioned in a recent letter, Prof. Schmidt, of Bonn, was elected chairman. The first address was read by Prof. Bier, who gave a historical review of sports, in which he referred to the high esteem in which the ancient Greeks and Romans held sports as factors in producing a healthy and strong youth. Sports in which the skin is freely exposed are a good prophylactic against diseases due to chill, against tuberculosis and rickets. In all forms of sport records are of less importance than good average results. Prof. Klapp spoke in favour of a daily hour of gymnastics in the schools, as is the rule in Sweden. Dr. Bruns, of Königsberg, read a paper on the influence of sports on the size of the heart. Prof. Strassmann spoke on the effect of sports on women, and said that in physically trained women delivery was as a rule more easy than in others. At the climacteric participation in sports counteracted obesity. The society elected a committee to examine the question of over-exertion.

Control of Tuberculous Patients.

According to the statistical tables published by the Statistical Office of the city of Berlin, 36,335 new cases of tuberculosis were examined last year in the municipal sanitary offices (Fürsorgestellen), together with 139,015 older cases. 142,503 visits in the homes of the patients have been made. Previous to the recent anti-tuberculosis law, 73 per cent. of the tuberculous patients were under the control of the offices, and it is hoped that under the new law the efficacy of the Fürsorgestellen will increase. They have worked and will continue to work together with the workmen's insurance institutions, being for the greater part connected with the municipal hospitals.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Politics and University Appointments.

IN this country the University and everything pertaining to it is maintained by the State, and the selection of teachers and the promotion to the title of privat-docent or professor is supposed to depend on scientific considerations only. Consequently, there was some consternation among the public when it became known that for the last three years a number of younger applicants for the posts of privat-docent or extraordinary professor had been rejected without explanation by the University Board. According to the law, the rejected applicant is entitled to learn the reason why he was deemed unfit for the post. This clear postulate of the rules and the law had not been complied with. In three instances, however, the unsuccessful candidates (one an assistant of the Institute for Physical Research, one a linguist, one an eminent student of hygiene) had received proof that they had been rejected simply because they had been suspected of being communists or social democrats. The Social Democratic (Labour) Party in our Parliament has taken the matter up and has lodged a complaint with the Government, demanding "that the rejected applications be reconsidered and that the meeting of the board of professors be controlled by a Government representative, as there can be no violation of the existing laws, which stipulate that no other considerations than the scientific qualifications of the applicant be decisive." At the same time all applicants, mostly medical men, who within the last three years had been unsuccessful are invited to report to the University committee of the Social Democratic Party so as to find out how the rather narrow-minded majority of the old professors had been administering the laws. It is well known that there is a secret tendency to keep out not only modern, free-minded young people, but also Jewish applicants or those of Jewish descent, no matter how well qualified they may be.

Public Baths and their Present Vogue.

A marked step forward in regard to public hygiene has been made in Vienna within the last five years by the opening of numerous bathing establishments for public use, some of them free of charge. The present municipal board of health is backed by the ruling political party in its endeavours to make Vienna the cleanliest, healthiest, and most hygienic of all capital cities in Europe. Thus Vienna owns 39 municipal bathing establishments, 18 douche baths each accommodating 280 visitors at a time, 3 swimming and warm baths, including Turkish baths, 13 river baths for swimming only, 5 children's baths (free of charge), besides 3 large open-air and sun baths. Whilst in 1888, when the first public douche baths were opened. only 80,000 visitors used them yearly, in 1923 no less than 4,840,000 visits were paid to the public municipal baths, including the air-and-sun baths. An illustrative fact may be mentioned. On July 15th, 1923, the total of paying visitors in these baths was 70.000—that is, almost as many on one day as were totalled all the year round 35 years ago. In the five children's baths over half a million children were counted last summer; five river baths. partly in the Danube in the centre of the city, partly in backwaters of the river on the outskirts of the town, have been opened lately. There the system of beach bathing is favoured —i.e., extensive sands and shallow water which is kept pure by the running stream—the bathers being able to enjoy at the same time the benefits of water, sunshine, and air. Three air-and-sun baths are situated on the slopes of the hills surrounding the city, thus adding to the air and sun therapy the beneficial effect of a fine view. Compulsory teaching of swimming for children will be introduced in the elementary schools within the next two years. All teachers of public schools are now expected to take courses in swimming, which are provided free of cost. At present the municipality is building a huge bathing establishment in the working men's district, which it is said will be the biggest and finest of its kind in Europe, so as to save the labourers the trouble and time of going to the baths situated rather far away from their district. Apart from these municipal establishments, we have, of course, a number of private institutions, which also offer excellent opportunities for swimming or bathing. But these are rather on a smaller scale, and their capacity is only a fraction of that offered by the municipal baths.

Blood Transfusion.

At a recent meeting of the Vienna Medical Society Dr. Redlich discussed the results obtained by the transfusion of healthy blood in five severe cases of pernicious anæmia. In all cases the condition of the patient was markedly improved by the procedure, as manifested by rapid increase of erythrocytes, a more satisfactory colour-index, and general improvement of the muscular tone. In a case of severe bilateral hæmorrhage from the kidneys, which had lasted for weeks and had been refractory to all other treatment, the transfusion soon put an end to the bleeding. The patients received, as a rule, between 300 and 500 c.cm. blood, and Dr. Redlich considers the repeated transfusion of large quantities at short intervals to be the most preferable method (8–10 days between each); smaller quantities and longer intervals are much less efficacious. The Öhlecker apparatus was used, and in all cases a compatibility test was made (method of Moss). Dr. Redlich stated that a slight rise of temperature was sometimes met with, but seemed to do no harm. In severe hæmorrhages the result was often excellent; but it was not known whether the results were permanent. A similar discussion took place some time ago in the Gynæcological Society of this city. Here, too, all were unanimous as to the good results obtainable by careful transfusion made after a preliminary blood test. In some cases a defibrinated or citrated blood did just as well as the direct transfusion. Prof. Eppinger pointed out that the increase of hæmolysis noted after the procedure showed that the newly ingested erythrocytes only lived for three or four days. He had also obtained very good results from intramuscular injection of blood. Cases of secondary anæmia were often much improved by transfusion and were thus made fit for a subsequent operation; and transfusion also gave good results in patients suffering from poisoning by domestic gas. But it must not be forgotten that, in urgent cases, the method is fraught with danger on account of possible anaphylactic shock. At present we have in Vienna a list of persons, belonging to four biological groups, who have consented to act as donors of blood for hospital cases. This system seems to work well.

The Anti-rat Campaign.

In the year 1921 the Board of Health of Austria organised an inquiry into the prevalence of rats in this country, especially in Vienna. It has been shown that apart from damage done to property by these mammals, no extensive epidemic could be traced here to them. Nevertheless, the possibility of an outbreak of plague is not out of question, since in Paris, as well as in Hamburg, a local "plague focus" is known to exist, due to the prevalence of rats, to say nothing of India. But as rats are on the increase here a campaign against them has been organised, and an Act has been brought in the National Assembly to deal with the economic and administrative measures required in the course of a rat campaign. Thus the expenses for the extermination of rats in infested private houses must be borne by the tenants, whilst in the public buildings (Customs House, granaries, General Post Office, and other Vienna buildings) the costs form an additional expense in the budget. It may be mentioned in this connexion that Austria has now been declared "clean" by the Immigration Board of the United States of America, so that emigrants from here are treated on the same footing as those coming from the countries with a clean hygienic bill (Great Britain, Germany, France, and Sweden). The Act gives full powers to the sanitary authorities to deal with all vermin whatever the cost.

UNQUALIFIED PRACTICE IN SWITZERLAND.

(FROM AN OCCASIONAL CORRESPONDENT.)

SWITZERLAND has the reputation of being an enlightened country, but dark corners remain, as was shown on August 17th, when the electorate of the Canton of Basle-Land with 5791 votes against 3531 gave its assent to a Bill brought forward by a certain number of citizens throwing open medical practice to "*homœopaths and herbalists.*" The Swiss Constitution leaves the supervision of medical practice to the cantonal authorities. The Federal Government sets up the standard, and provides arrangements for the examinations, for a State medical diploma, but recognition of the diploma rests with cantonal authorities. Of the 25 Swiss cantons up till recently 24 grant the licence to practise medicine exclusively to holders of the Federal diploma. In the canton of Appenzell-Ausser-Rhoden medical practice was always free. "The practice of the medical and veterinary profession is free, and no person enjoying civic rights can be prohibited from exercising these professions." "Higher operative surgery, midwifery, medico-legal functions" are reserved for qualified practitioners by means of by-laws, but the canton of Appenzell has become a perfect Eldorado of quacks, having 26 qualified doctors and 35 unqualified practitioners. The latter do not confine their activities to their own canton, but carry on an extensive postal and consulting practice throughout the country. Every oriental and occidental medical system, as was recently shown in an address by Dr. Hunziker, health officer of Basle City, is represented amongst them. Arabian medicine-men, magnetotherapists, electrotherapists, spagirists, herbalists, "eye diagnosticians," psychophytotherapists, and phrenologists advertise their trade. One of them describes himself as court physician to the Sultan of Perak, another as professor of the University of Lima. Some diagnose all ailments exclusively by the examination of the urine. It has been learnt from a trustworthy source that one of them used to test a hundred samples of urine in half an hour, and to write as many prescriptions in the same time. Others never see their patients; they only require a sample of urine, after which they send their diagnosis and medicament by return of post and charge a heavy fee. Dr. Hunziker inquired into the original occupations of these unqualified practitioners, and found among them farmers, innkeepers, clerks, clergymen, cobblers, architects, hairdressers, coachmen, policemen, journalists, tramcar conductors, butchers, musicians, and midwives.

Mr. Howard Eugster, director of the Appenzell Health Department, has publicly regretted the state of affairs in his canton. But Appenzell has an advanced democratic constitution, and to alter the present regulations concerning medical practice a referendum would be necessary, and at present the chances of a favourable issue of such a vote are very small, as "freedom" of medical practice is widely regarded as a democratic achievement; and the unqualified practitioners are firmly entrenched in popular esteem. Moreover, they have begun to organise themselves and to carry on propaganda. That propaganda was not restricted to their own canton. Last year an effort was made to throw open the canton of Glaris, but there the proposition was vetoed by way of the plebiscite. This year it was the turn of the canton of Basle-Land, the population of which was always inclined to this sort of medical treatment. It must be noted that the cantons of Appenzell, Glaris, and Basle-Land alike have no towns and the population is purely rural. The new compulsory additional lectures on hygiene, orthopædics, and forensic medicine. The State examination will include 14 sections—namely, pathology and post-mortem examination, topographical anatomy, pharmacy, internal medicine, surgery, obstetrics and women's diseases, ophthalmology, diseases of the ears, the pharynx, and the nose, children's diseases, diseases of the skin, venereal diseases, psychiatry, hygiene, and forensic medicine. If a candidate fails in passing the examination at the first attempt, he may re-enter for it only once. The practical year subsequent to the State examination has been retained under the regulations; during the practical year the candidate must prove that he is able to give a professional opinion in forensic cases.

The Anti-Opium Law.

The German Parliament has recently passed a Bill dealing with the import, the export, and the sale of opium in accordance with the international conventions on that subject. According to the provisions of the Bill, raw and refined opium (morphine, heroin, &c.) may only be imported by chemical works and wholesale dealers who do not sell their products to the individual consumer; this special licence may be granted only to persons of good conduct and to recognised scientific institutions. From a medical point of view the principal feature of the law is that medical prescriptions containing opium may not be given back to patients, but are to be retained in the pharmacy; they must be produced on request of the district medical officer of health. In this way it will become difficult, if not impossible, for people who indulge in the morphia habit to procure morphine in several pharmacies by one single written prescription. The export of opium to foreign countries is permitted only when the Government in question has given its agreement, and this agreement is produced to the competent German authority. The import and export of opium for smoking purposes is strictly prohibited in accordance with the international conventions: offenders against this and the other provisions of the law may be punished with imprisonment not exceeding three years, and a fine.

The Society for Sports.

At the inaugural meeting of the newly founded Society for Sports (vide THE LANCET, July 5th, 1924, p. 40) which I mentioned in a recent letter, Prof. Schmidt, of Bonn, was elected chairman. The first address was read by Prof. Bier, who gave a historical review of sports, in which he referred to the high esteem in which the ancient Greeks and Romans held sports as factors in producing a healthy and strong youth. Sports in which the skin is freely exposed are a good prophylactic against diseases due to chill, against tuberculosis and rickets. In all forms of sport records are of less importance than good average results. Prof. Klapp spoke in favour of a daily hour of gymnastics in the schools, as is the rule in Sweden. Dr. Bruns, of Königsberg, read a paper on the influence of sports on the size of the heart. Prof. Strassmann spoke on the effect of sports on women, and said that in physically trained women delivery was as a rule more easy than in others. At the climacteric participation in sports counteracted obesity. The society elected a committee to examine the question of over-exertion.

Control of Tuberculous Patients.

According to the statistical tables published by the Statistical Office of the city of Berlin, 36,335 new cases of tuberculosis were examined last year in the municipal sanitary offices (Fürsorgestellen), together with 139,015 older cases. 142,503 visits in the homes of the patients have been made. Previous to the recent anti-tuberculosis law, 73 per cent. of the tuberculous patients were under the control of the offices, and it is hoped that under the new law the efficacy of the Fürsorgestellen will increase. They have worked and will continue to work together with the workmen's insurance institutions, being for the greater part connected with the municipal hospitals.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Politics and University Appointments.

IN this country the University and everything pertaining to it is maintained by the State, and the selection of teachers and the promotion to the title of privat-docent or professor is supposed to depend on scientific considerations only. Consequently, there was some consternation among the public when it became known that for the last three years a number of younger applicants for the posts of privat-docent or extraordinary professor had been rejected without explanation by the University Board. According to the law, the rejected applicant is entitled to learn the reason why he was deemed unfit for the post. This clear postulate of the rules and the law had not been complied with. In three instances, however, the unsuccessful candidates (one an assistant of the Institute for Physical Research, one a linguist, one an eminent student of hygiene) had received proof that they had been rejected simply because they had been suspected of being communists or social democrats. The Social Democratic (Labour) Party in our Parliament has taken the matter up and has lodged a complaint with the Government, demanding "that the rejected applications be reconsidered and that the meeting of the board of professors be controlled by a Government representative, as there can be no violation of the existing laws, which stipulate that no other considerations than the scientific qualifications of the applicant be decisive." At the same time all applicants, mostly medical men, who within the last three years had been unsuccessful are invited to report to the University committee of the Social Democratic Party so as to find out how the rather narrow-minded majority of the old professors had been administering the laws. It is well known that there is a secret tendency to keep out not only modern, free-minded young people, but also Jewish applicants or those of Jewish descent, no matter how well qualified they may be.

Public Baths and their Present Vogue.

A marked step forward in regard to public hygiene has been made in Vienna within the last five years by the opening of numerous bathing establishments for public use, some of them free of charge. The present municipal board of health is backed by the ruling political party in its endeavours to make Vienna the cleanliest, healthiest, and most hygienic of all capital cities in Europe. Thus Vienna owns 39 municipal bathing establishments, 18 douche baths each accommodating 280 visitors at a time, 3 swimming and warm baths, including Turkish baths, 13 river baths for swimming only, 5 children's baths (free of charge), besides 3 large open-air and sun baths. Whilst in 1888, when the first public douche baths were opened, only 80,000 visitors used them yearly, in 1923 no less than 4,840,000 visits were paid to the public municipal baths, including the air-and-sun baths. An illustrative fact may be mentioned. On July 15th, 1923, the total of paying visitors in these baths was 70,000—that is, almost as many on one day as were totalled all the year round 35 years ago. In the five children's baths over half a million children were counted last summer; five river baths, partly in the Danube in the centre of the city, partly in backwaters of the river on the outskirts of the town, have been opened lately. There the system of beach bathing is favoured—i.e., extensive sands and shallow water which is kept pure by the running stream—the bathers being able to enjoy at the same time the benefits of water, sunshine, and air. Three air-and-sun baths are situated on the slopes of the hills surrounding the city, thus adding to the air and sun therapy the beneficial effect of a fine view. Compulsory teaching of swimming for children will be introduced in the elementary schools within the next two years. All teachers of public schools are now expected to take courses in swimming, which are provided free of cost. At present the municipality is building a huge bathing establishment in the working men's district, which it is said will be the biggest and finest of its kind in Europe, so as to save the labourers the trouble and time of going to the baths situated rather far away from their district. Apart from these municipal establishments, we have, of course, a number of private institutions, which also offer excellent opportunities for swimming or bathing. But these are rather on a smaller scale, and their capacity is only a fraction of that offered by the municipal baths.

Blood Transfusion.

At a recent meeting of the Vienna Medical Society Dr. Redlich discussed the results obtained by the transfusion of healthy blood in five severe cases of pernicious anæmia. In all cases the condition of the patient was markedly improved by the procedure, as manifested by rapid increase of erythrocytes, a more satisfactory colour-index, and general improvement of the muscular tone. In a case of severe bilateral hæmorrhage from the kidneys, which had lasted for weeks and had been refractory to all other treatment, the transfusion soon put an end to the bleeding. The patients received, as a rule, between 300 and 500 c.cm. blood, and Dr. Redlich considers the repeated transfusion of large quantities at short intervals to be the most preferable method (8–10 days between each); smaller quantities and longer intervals are much less efficacious. The Öhlecker apparatus was used, and in all cases a compatibility test was made (method of Moss). Dr. Redlich stated that a slight rise of temperature was sometimes met with, but seemed to do no harm. In severe hæmorrhages the result was often excellent; but it was not known whether the results were permanent. A similar discussion took place some time ago in the Gynæcological Society of this city. Here, too, all were unanimous as to the good results obtainable by careful transfusion made after a preliminary blood test. In some cases a defibrinated or citrated blood did just as well as the direct transfusion. Prof. Eppinger pointed out that the increase of hæmolysis noted after the procedure showed that the newly ingested erythrocytes only lived for three or four days. He had also obtained very good results from intramuscular injection of blood. Cases of secondary anæmia were often much improved by transfusion and were thus made fit for a subsequent operation; and transfusion also gave good results in patients suffering from poisoning by domestic gas. But it must not be forgotten that, in urgent cases, the method is fraught with danger on account of possible anaphylactic shock. At present we have in Vienna a list of persons, belonging to four biological groups, who have consented to act as donors of blood for hospital cases. This system seems to work well.

The Anti-rat Campaign.

In the year 1921 the Board of Health of Austria organised an inquiry into the prevalence of rats in this country, especially in Vienna. It has been shown that apart from damage done to property by these mammals, no extensive epidemic could be traced here to them. Nevertheless, the possibility of an outbreak of plague is not out of question, since in Paris, as well as in Hamburg, a local "plague focus" is known to exist, due to the prevalence of rats, to say nothing of India. But as rats are on the increase here a campaign against them has been organised, and an Act has been brought in the National Assembly to deal with the economic and administrative measures required in the course of a rat campaign. Thus the expenses for the extermination of rats in infested private houses must be borne by the tenants, whilst in the public buildings (Customs House, granaries, General Post Office, and other Vienna buildings) the costs form an additional expense in the budget. It may be mentioned in this connexion that Austria has now been declared "clean" by the Immigration Board of the United States of America, so that emigrants from here are treated on the same footing as those coming from the countries with a clean hygienic bill (Great Britain, Germany, France, and Sweden). The Act gives full powers to the sanitary authorities to deal with all vermin whatever the cost.

UNQUALIFIED PRACTICE IN SWITZERLAND.

(FROM AN OCCASIONAL CORRESPONDENT.)

SWITZERLAND has the reputation of being an enlightened country, but dark corners remain, as was shown on August 17th, when the electorate of the Canton of Basle-Land with 5791 votes against 3531 gave its assent to a Bill brought forward by a certain number of citizens throwing open medical practice to "homœopaths and herbalists." The Swiss Constitution leaves the supervision of medical practice to the cantonal authorities. The Federal Government sets up the standard, and provides arrangements for the examinations, for a State medical diploma, but recognition of the diploma rests with cantonal authorities. Of the 25 Swiss cantons up till recently 24 grant the licence to practise medicine exclusively to holders of the Federal diploma. In the canton of Appenzell-Ausser-Rhoden medical practice was always free. "The practice of the medical and veterinary profession is free, and no person enjoying civic rights can be prohibited from exercising these professions." "Higher operative surgery, midwifery, medico-legal functions" are reserved for qualified practitioners by means of by-laws, but the canton of Appenzell has become a perfect Eldorado of quacks, having 26 qualified doctors and 35 unqualified practitioners. The latter do not confine their activities to their own canton, but carry on an extensive postal and consulting practice throughout the country. Every oriental and occidental medical system, as was recently shown in an address by Dr. Hunziker, health officer of Basle City, is represented amongst them. Arabian medicine-men, magnetotherapists, electrotherapists, spagirists, herbalists, "eye diagnosticians," psychophytotherapists, and phrenologists advertise their trade. One of them describes himself as court physician to the Sultan of Perak, another as professor of the University of Lima. Some diagnose all ailments exclusively by the examination of the urine. It has been learnt from a trustworthy source that one of them used to test a hundred samples of urine in half an hour, and to write as many prescriptions in the same time. Others never see their patients; they only require a sample of urine, after which they send their diagnosis and medicament by return of post and charge a heavy fee. Dr. Hunziker inquired into the original occupations of these unqualified practitioners, and found among them farmers, innkeepers, clerks, clergymen, cobblers, architects, hairdressers, coachmen, policemen, journalists, tramcar conductors, butchers, musicians, and midwives.

Mr. Howard Eugster, director of the Appenzell Health Department, has publicly regretted the state of affairs in his canton. But Appenzell has an advanced democratic constitution, and to alter the present regulations concerning medical practice a referendum would be necessary, and at present the chances of a favourable issue of such a vote are very small, as "freedom" of medical practice is widely regarded as a democratic achievement; and the unqualified practitioners are firmly entrenched in popular esteem. Moreover, they have begun to organise themselves and to carry on propaganda. That propaganda was not restricted to their own canton. Last year an effort was made to throw open the canton of Glaris, but there the proposition was vetoed by way of the plebiscite. This year it was the turn of the canton of Basle-Land, the population of which was always inclined to this sort of medical treatment. It must be noted that the cantons of Appenzell, Glaris, and Basle-Land alike have no towns and the population is purely rural. The proposition agreed in the popular vote is to throw open the practice of non-toxic herbalist and homœopathic methods (Ausübung der giftfreien Kräuter- und homœopathischen Heilmethode), with the exclusion of surgery and midwifery. The requirements for such practitioners are that they must enjoy full civic rights and a residence in the canton for two years previous to their practice. After the adoption of this proposition the by-laws of public health must be altered accordingly, and then the people must again decide over the amended by-laws. In this way the plebiscite is not final, and the hope of a more enlightened vote can still be entertained. Practice for members of insurance societies will be restricted in any case to qualified medical men as before.

The Basle plebiscite of August 17th has been widely discussed. It is best explained as a natural, however ill-directed, reaction against State interference with individual freedom. The determined resistance against compulsory vaccination is explained by the same tendency. In addition, there is undoubtedly a certain popular mistrust of medical science and of the medical profession. In the canton of Zurich exists a strong movement for abolition of vivisection. The electorate will soon be called to give its verdict on this question.

UNITED STATES OF AMERICA.

(From an Occasional Correspondent.)

The Framingham Demonstration.

After seven years of intensive work the organisers of the Framingham Demonstration have withdrawn. Nearly all of their work for the public health will be taken over by private or official agencies in the locality. The local board of health has in these years increased its expenditure from $8000 to $20,000 per annum, and, we may be sure, is not dissatisfied with the investment. The death-rate for the last two years is 9 per cent. below that for the decennial period preceding the demonstration. This is largely accounted for by a drop of 40 per cent. in infant mortality and 68 per cent. in tuberculosis. Seven "control" towns, whose mortality was comparable to and corrected on the same basis as that of Framingham, showed in the same period a reduction of only 32 per cent. in the tuberculosis mortality. Some account of how these fine results were accomplished has already appeared in your columns,[1] and a great deal of additional material, including valuable statistics, will be found in the final summary report which has just been issued and which may be obtained through the National Tuberculosis Association.[2] The care with which the different phases of the experiment have been classified and the addition of a good index will make this report a particularly valuable handbook to speakers on public health.

Scarlet Fever Prevention.

The health authorities are losing no time in turning to practical account the newer knowledge of the ætiology and immunology of scarlet fever. The New York City Department of Health announces in its weekly bulletin that it is prepared to immunise with Dochez's serum all children who have been exposed to infection with scarlet fever. Throat cultures for scarlet fever streptococci are being taken and the Dick skin test made. The Ohio Department of Health is considering the advisability of combining a Dick test campaign with its present State-wide campaign of Schick testing. It is less than two months since the Drs. Dick pointed out at the annual convention of the American Medical Association that "since scarlet fever toxin can be properly standardised only by means of skin tests on a large number of human beings, it is almost certain that improperly standardised toxin will appear on the market." While I am not aware of the method by which this difficulty has been overcome, it is evident that some means must have been discovered.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The following table gives some of the principal health statistics of four counties for 1923:—

Name of county.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Surrey	740,800	16·0	9·7	0·7	1·4	1·4	26	45	2·7
Wiltshire ..	290,880	18·3	11·0	0·8	1·5	1·4	32	51	2·4
Warwickshire	351,800	19·7	10·3	0·8	1·1	1·6	33	60	2·9
Northamptonshire	214,331	17·1	11·5	0·9	1·4	1·6	31	61	5·7

Surrey.

Dr. Joseph Cates describes the consideration given by the county council to the scheme for making more adequate provision for the institutional treatment of tuberculosis. The difficulties arising from the present arrangements are that most of the beds available are outside the county, and cause a natural reluctance in patients and their friends to accept treatment at a distant locality. The public health committee now recommend the carrying out of their original scheme for the erection of a sanatorium at Milford on the site purchased before the war. The proposed sanatorium will have accommodation for 200 patients and the expenditure is not to exceed £80,000. For the treatment of venereal diseases the county council provide clinics at the County Hospital, Guildford, and the Royal Hospital, Richmond, and also share in the joint agreement for using the London hospitals. Referring to midwifery practice by handy-women, Dr. Cates says this illegal practice would have ceased long ago but for the fact that certain medical practitioners knowingly render handy-women assistance by notifying births, signing certificates, and generally by shouldering the responsibility for the disasters which occur from time to time. As regards housing, Dr. Cates says there is no evidence that the overcrowding which existed in Surrey in the year 1922 has appreciably diminished. Reference is made to the large number of foods to which preservatives are now added, and the county analyst draws attention to the increasing practice of adding "improvers" to flour. The principal effect of the use of an "improver" is to enable more loaves to be made from a sack of flour, or in other words, to enable the baker to bake a flour containing a higher proportion of water. Only one producer has been licensed by the county council for "Grade A" milk, though it is clear that the standard required is attainable by any farmer who produces his milk under proper hygienic conditions. Dr. Cates thinks it is a question if the time has not come to consider whether the sale of milk falling below the standard of "Grade A" should any longer be permitted.

An appendix gives an interesting report of the condition of the River Wandle from its source near Croydon to its outfall into the Thames at Wandsworth. The upper part of the river receives a good deal of surface water polluted with oil and tar, and it is stated that since the pollution with oil and tar the water-cress beds adjoining the river do not flourish. Originally the Wandle was noted for its trout, but experiments by riparian owners in recent years to stock parts of the river with fish have failed, presumably owing to the tar, oil, and chemicals discharged into the river. The banks of the river are not well kept in all cases and the flow of the stream is sometimes much impaired. In the neighbourhood of Wimbledon the river is grossly polluted with sewage, chiefly from the works of the Wandle Valley Joint Sewage Board. Dr. Cates recommends that steps be taken for the establishment of a Wandle River Board and that a meeting of all the local sanitary authorities of the districts through which the river flows be called to discuss this proposal. Pending the establishment of such a board he recommends the county council to take proceedings to prevent gross contamination of the Wandle.

In the school report Dr. Cates describes the negotiations which have taken place with the Board of Education to make the dental scheme as complete as possible. The present school dental staff consists of four whole-time and one part-time dental surgeon, who are capable of dealing with 17,000 inspections and 4000 treatments per annum. Each age-group consists of about 7000 children, and one dentist is equal to dealing with half an age-group. It is obvious that many more dentists will be required to deal with the 62,000 children on the register. Dr. Cates discusses a complete scheme for mentally abnormal school-children. The essential unit, he says, is the residential colony, which would receive idiots, imbeciles, low-grade feeble-minded children, and also high-grade feeble-minded children who do not make substantial progress at the day special school. The larger public elementary schools should each have classes for dull and backward children. Those who made no progress in such classes would be transferred to a special day-school. One colony might serve the whole county and three special day-schools in areas such as Mitcham, Barnes, and Woking might be sufficient.

Wiltshire.

Dr. Claude E. Tangye shows that certified midwives attended about 63 per cent. of the confinements in the county and sent for medical aid in about 20 per cent. of their cases. He mentions the curious fact that there are usually fewer cases of puerperal fever in the practice of the bona-fide midwives than in the practice of the trained midwives. Thus in 1923 there were no cases of puerperal fever in connexion with the 824 confinements attended by bona-fide midwives, while there were six cases among the 2600 confinements attended by trained midwives and three cases among the 1999 confinements attended by doctors. The county council make payments to some 70 district nursing associations and to six certified midwives. The subsidised midwives provide for areas otherwise unserved, and the rest of such areas have their needs met by the county council paying the travelling expenses of neighbouring midwives or by the admission of cases to the subsidised maternity homes. The maternity beds subsidised by the county council are at the Malmesbury Cottage Hospital, Salisbury General Infirmary, and the homes at Corsham and Swindon. Dr. Tangye shows that a reconsideration of the hospital areas and the isolation hospital accommodation in the county is necessary both for the sake of economy and efficiency. As the result of a public inquiry the county council was, in November, constituted the authority for dealing with small-pox within the county. The Salisbury Small-pox Hospital is to be acquired by the county council to serve the south of the county and a new hospital is to be built at Ogbourne to serve the north. Dr. Tangye mentions that, as in previous years, very little has been done in some districts in the inspection of houses or in obtaining repairs of dilapidated property. Only 481 new houses in all were erected during the year as against 899 in 1922.

Warwickshire.

Dr. A. Hamilton Wood records the praiseworthy efforts of the county council to prevent river pollution. A survey of the Tame made in July, 1923, showed that the oxygen content of the river was so low that fish life was impossible throughout its entire course. The Tame is a seriously polluted river before it reaches the county boundary, and notwithstanding the beneficial effect of the junction with the Anker, it leaves Warwickshire to re-enter the county of Stafford still polluted. The effluent from the Birmingham, Tame and Rea drainage works was of fair quality during the year, but its chlorinous odour was objectionable to those living on the banks of the river. There were indications of a slight improvement in the water. A survey of the Anker showed serious pollution from the brook which receives the effluent from the Hinckley sewage works. Improvements are being introduced at the Nuneaton sewage works, and other works whose effluents discharge into the Anker. Efforts are also being made to deal with the trade waste from the Sketchley dye works. The Avon enters the county near Rugby as a comparatively small stream and is soon polluted by the Rugby sewage works, which are now being improved. At Coventry the river with a normal flow of less than 10,000,000 gallons receives 5,000,000 gallons of unsatisfactory effluent from the sewage works, and Dr. Wood hopes the Coventry authorities will realise their responsibilities in the matter. An improvement is expected when the bio-aeration plant in course of construction is in operation, probably during the autumn of the present year. The Warwick sewage farm also turns an unsatisfactory effluent into the Avon, and it is imperative, says Dr. Wood, that the borough council should immediately take steps to bring about an improvement.

The widespread epidemics of paratyphoid fever which occurred during the summer centred around Leamington Spa. The source of infection was supposed to be a carrier, whose removal from the district coincided with the cessation of the epidemic. Mention is made of a letter from the Ministry in December suggesting coöperation between after-care committees, the Ministry of Pensions, the King's Roll Committee, and the Ministry of Labour in the endeavour to find suitable employment for ex-sanatorium patients. It is recommended that when possible six weeks' notice should be given of the pending discharge of a patient and that the tuberculosis officer should notify the local employment exchange when a change of occupation is necessary and at the same time forward a list of occupations which are considered unsuitable for the patient. Antenatal clinics have been established by the county council at Warwick and Rugby in connexion with their maternity homes and there are also small clinics at Stoke Heath and Solihull. The attendance of new cases during the year numbered 121, so that this work is only beginning. Dr. Wood points out that the health visitors were reduced in number from 18 to 16 in 1921 and that their work is suffering in consequence.

Northamptonshire.

Dr. Charles E. Paget reports that with the object of a better coördination of health services a special committee of the British Medical Association has been appointed to act as a liaison committee between the county council and the practitioners of the county. The arrangement by which the district nurses of the Northamptonshire District Nursing Association undertake the health visiting in the Brackley area is to be continued for a further period, but such services are to be subject to the supervision of the officers of the county council dating from June 1st, 1923. The county council coöperated with the Insurance Committee in the effective keeping of Health Week, and special celebrations were carried out in the selected centres of Irthlingborough, Oundle, Rothwell, and Rushden. Dr. Paget points out that the increase in cancer among females synchronised with the grave anxieties experienced under home conditions during the war and in the years following, and that there was no marked general increase in the male mortality from cancer until after the conclusion of the war. There was a small outbreak of five cases [illegible] ente fever in one house in the Brackley ru traceable to a sewage polluted well wl to have been infected by an unsuspected carrier staying in the house. There was no need for anyone to use the well for drinking purposes as a public supply of pure water was available for the occupants of the house.

An arrangement is in force with the County Nursing Association for the services of a nurse when a district is attacked by measles. Accommodation for the emergency nurse is to be provided through the district medical officer of health. Although measles was more prevalent than in the previous year, Dr. Paget regrets that no district took advantage of this arrangement. No progress has been made during the year in providing for the isolation of ordinary infectious diseases. A conference was held in November to which delegates from all the local sanitary authorities were invited for the purpose of considering the best means of providing small-pox accommodation for every district in the county. The attitude of the county council towards this question will depend upon the outcome of the discussions which ensued. Dr. Paget thinks the shortage of houses is likely to continue while the present prices for building materials are maintained and dilution within the industry in respect of skilled operatives does not take place. Several districts in the county have schemes in operation for the inspection of milch-herds by veterinary surgeons. In the Kettering, Desborough, and Rothwell districts four cows with tuberculous udders were found among 3730. In the Wellingborough district 38 out of 3316 cows were found to have abnormal udders, and in 19 of the 38 the cows were tuberculous. In the Kettering Urban District a scheme is in satisfactory operation by which the butchers give notice of their intention to slaughter in order to facilitate inspection, the individual butchers being protected against loss by an insurance scheme.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 23RD, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 44; scarlet fever, 1275; diphtheria, 623; enteric fever, 81; pneumonia, 390; puerperal fever, 46; cerebro-spinal fever, 5; acute poliomyelitis, 35; acute polio-encephalitis, 1; encephalitis lethargica, 64; continued fever, 1; dysentery, 3; ophthalmia neonatorum, 112. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from enteric fever, 1 from small-pox; 7 from scarlet fever; 29 from diphtheria; 11 from measles; 17 from influenza. In London itself the diphtheria deaths numbered 10. The fatal case of small-pox was reported from Barnsley. Previous fatal cases of small-pox during the quarter were reported, 3 in the week ended July 5th, 1 in the week ended June 28th. The actual number of cases of small-pox reported during the 13 weeks up to and including August 23rd was 336.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the committee 35 cases were considered and £507 10*s.* voted to 34 applicants. The following is a summary of some of the new cases relieved:—

Widow, aged 52, of M.R.C.S. who practised at Westbury and died this year. Late husband's practice has been sold and the payment to be spread over three years. When everything is settled applicant hopes to get an income about £90 per annum. The three children get an income of £13 16*s.* 8*d.* each. Applicant is unable to earn her own living owing to the care of an imbecile daughter aged 26. Voted £20.

Daughter, aged 60, of M.R.C.S. Eng. who practised at Andover and died in 1869. Has had no regular work since 1923 and is now considered too old for the posts she applies for. From 1915 to 1923 was nurse at a rescue maternity home, but on the resignation of the superintendent lost her post owing to the new superintendent bringing her own nurse. Is at present living with a married sister whose husband is a retired clergyman of over 80 years of age with two small pensions and unable to help his sister-in-law. Applicant has been doing knitting, for which she expects to receive 15*s.* She has one month's temporary work in view at 15*s.* a week. Voted £26 in 12 instalments.

Widow, aged 72, of M.D. Irel. who practised at Everton and died in 1894. Applicant left her husband in 1881 through his intemperance and supported herself and son. A few years ago obtained an annuity of £10 from Liverpool Merchants' Guild, which is her only income apart from the money received by knitting, which came to 29*s.* She lives with two unmarried sisters who are not well off. Voted £26 in 12 instalments.

Daughter, aged 37, of L.R.C.P. Edin. who practised in Liverpool and died in 1911. Suffers from epilepsy and is looked after by a sister whose only income is £17 10*s.* a year, the same as the applicant's. Applicant is only able to do temporary light clerical work at times, and the last 12 months only earned £8 10*s.*, and Lady Barr sent £5. Voted £15.

Daughter, aged 82, of M.R.C.S. Eng. who practised in North London and died in 1892. Applicant opened a home of rest for young women and carried it on until 1922 when her health broke down, which compelled her to give up everything. She now lives in one room in her sister's house. Applicant is living on her savings and all she has to depend on is the old age pension, 8*s.* a week, and interest on £100 War Bonds. Voted £10.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., C.B., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: G. E. Hamilton to *Fisgard;* A. R. Davidson to *Resolution;* and J. C. Bringan to *Victory*, for R.N. Barracks, Portsmouth; K. H. Hole to *Frobisher*, and as Squadron Medical Officer, on commg.; and J. O'Flynn to *President*, addl., for three months' hospl. course (on relief).

Surg. Lt.-Comdrs.: T. Gwynne-Jones to *Victory*, for R.N. Barracks; D. P. H. Pearson to *Queen Elizabeth;* A. G. Taylor to R.N. Sick Quarters, Shotley; F. G. Hunt to *Mackay;* L. W. Gemmell to R.N. Hospl., Chatham; R. K. Shaw to *Endeavour;* F. St. B. Wickham to *Assistance;* G. Aubrey to R.N. Hospl., Chatham; A. C. V. Green to *Burslem;* N. B. de M. Greenstreet to *Hermes;* and E. Heffernan to R.N. Hospl., Plymouth.

Surg. Lts.: R. R. Baker to *Iron Duke;* M. Barton to *Adamant;* and J. J. A. O'Sullivan to *Royal Oak;* C. H. Savory to *Victory*, for Portsmouth Dockyard, temp., and to *Frobisher* on commg.; D. Glass to *Wallace;* and J. J. O'Reilly to *Resolution*.

R. Burns to be Surg. Lt.

ROYAL NAVAL VOLUNTEER RESERVE.

Late Temp. Surg. Sub-Lt. A. S. Bradlaw, entered as Proby. Surg. Lt., and attached to the Bristol Division.

Proby. Surg. Sub-Lts. H. O'Connor and R. A. Pallister to *Tiger*, addl., for 28 days' training (appt. to *Cyclops* cancelled).

ROYAL ARMY MEDICAL CORPS.

Maj. A. B. Murray, having attained the age limit, is retd. and retains the rank of Maj. with permission to wear the prescribed uniform.

Maj. A. W. Gater retires on retd. pay and is granted the rank of Lt.-Col.

Temp. Capt. H. C. Beasley and Temp. Capt. T. B. A. Haggard relinquish their commns. and retain the rank of Capt.

The undermentioned Majs. to be Lt.-Cols.: J. Mackenzie, vice Lt.-Col. A. A. Seeds, to retd. pay; N. D. Walker, vice Lt.-Col. F. J. Brakenridge, promoted.

Maj. and Bt. Lt.-Col. H. J. Crossley to be Lt.-Col., vice Lt.-Col. N. J. C. Rutherford, promoted.

Col. C. B. Martin, late R.A.M.C., retires on retd. pay.

Royal Army Medical College: Col. C. W. Mainprise, late R.A.M.C., has been appointed Comdt.

TERRITORIAL ARMY.

General Hospitals: Capt. G. J. Linklater (late R.A.M.C., T.F.) to be Capt.; Lt. G. A. Fisher to be Capt. (Prov.); Lt. C. A. Cowie (late Gordon Highlanders (T.A.)) to be Lt.

Supernumerary for Service with the O.T.C.: Capt. W. E. Le Gros Clark (late R.A.M.C., S.R.) to be Capt.

Capt. W. T. Briscoe to be Maj.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. F. Hawthorn, from Active List, to be Lt.-Col.

INDIAN MEDICAL SERVICE.

Lt.-Col. N. J. C. Rutherford, from R.A.M.C., to be Col., vice Col. C. B. Martin, to ret. pay.

The King has been pleased to give and grant unto Dr. Charles Todd, Technical Expert to the Egyptian Department of Public Health, His Majesty's Royal licence and authority to wear the Insignia of the Second Class of the Order of the Nile, which decoration has been conferred upon him by the King of Egypt in recognition of valuable services rendered by him.

Correspondence.

"Audi alteram partem."

CARDIAC DISEASE AND WORK.

To the Editor of THE LANCET.

SIR,—In the out-patient practice of a hospital, and also to a less extent in private practice, the main question in regard to heart disease for a patient who is not bedridden is the finding of a suitable occupation. Thirty years ago, when a student, I was impressed mainly with the importance of rest in heart disease, and the help afforded by digitalis in cases of cardiac breakdown. Medical opinion would now seem to have moved to the opposite extreme, and to be mainly impressed by the importance of exercise in heart disease. True, indeed, as far back as 1890 Oertel had suggested the advisability of mild hill-climbing in cases of heart disease, which was followed later by the exploitation of the Nauheim baths and remedial exercises. It is now generally realised that hearts may be underworked as well as overworked. As a rule, the term disease seems to imply something which is progressive; now there are numerous cardiac affections which, though the result of disease, would be better regarded as disabilities, just as a man who has had infantile paralysis suffers from a disability which is the result of a disease, but can no longer be regarded as having a disease.

In considering the question of work, the problem is how, after all acute conditions have subsided and all probability of a cardiac breakdown averted, with the minimum amount of departure from his ordinary activities, a patient with disease of the heart can make the best of himself. Without definitely trying, it is not easy to say what occupations are fitting and what are not for a patient with cardiac disease, so extremely individual is the lesion. There are, however, certain general principles which may be usefully observed in guiding a patient with cardiac disease to the right occupation. Needless to say, a man, wherever it is possible, should continue at the work to which he is accustomed, for even though the work may be comparatively heavy, he will by long use and wont have acquired the knack of economising his energy so that for him the work may be admissible.

There are, doubtless, certain conditions of work which are unfavourable to most cases of cardiac disease.

1. All occupations involving sudden jerks or spurts and periodical rushes—soldiers, sailors, dock labourers, stokers, &c.

2. Occupations which require frequent stair-climbing or running errands.

3. Prolonged standing such as is required by salesmen.

4. Occupations which involve frequently moving from hot to cold rooms and vice versa—this is particularly unfavourable for such patients as are liable to attacks of angina.

5. Conditions which require work to be done in an overheated atmosphere, such as tobacco drying, or working in large scale cucumber frames.

6. Occupations requiring much use of the arms. Often patients with cardiac disease can walk for considerable distances and indulge in other such forms of exertion with impunity, while anything which requires quite a slight use of the arms, such as dressing or carrying a light bag, may be prejudicial to them. The case of a music teacher came before me, who could do her teaching quite satisfactorily, but a small amount of actual playing herself soon exhausted her.

7. Outside work, as a rule, is much heavier than work indoors, and though it may have some advantages, one must remember that the benefits of the air are often counterbalanced by the changes of temperature and the dangers of getting wet, for those who have rheumatic tendencies and are susceptible to colds and bronchitis.

8. Some occupations are more likely to induce psychic disturbances than others, and these should be particularly avoided by cardiac patients.

It might seem from the above as though there would not be many occupations open to patients with heart disease, and, no doubt, for the absolutely unskilled manual labourer the outlook is an unfavourable one; on the other hand, the tendency nowadays is for work to become less and less entirely unskilled. Apart from the numerous forms of work which come under the head of "clerical," the following occupations are fairly suitable for most forms of cardiac disease.

1. Tailoring.
2. Some forms of bootmaking.
3. Basket-making.
4. Leather work.
5. Telephone operating.
6. Piano factories, "assembling small parts."
7. Fountain-pen factories.
8. Painting.*

* As this often necessitates going up ladders it will not be suitable for cases with aortic disease who are liable to fainting attacks.

In all occupations one of the most important things to consider is the regularity of the hours as well as the actual amount of work to be done, also whether the man has to travel far to his work, involving hurry to catch train, tram, or 'bus. In any given case when selecting an occupation for a patient with cardiac disease, we should carefully consider the cause of the cardiac lesion, for, if it is a valvular lesion, the result of some rheumatic affection, though there is a risk of a recurrent attack and possible further damage to the heart, yet, on the whole, such cases can often do fairly hard work, whereas when the cardiac condition is the result of myocardial degeneration, the amount of work which can be obtained from such cases is much more moderate. As yet we are hardly in a position to interpret the degree of heart weakness in terms of industrial effort.

I am, Sir, yours faithfully,

Montagu-square, W., August 28th, 1924. R. O. MOON.

"ON THE BREAST": AN EXPLANATION.

To the Editor of THE LANCET.

SIR,—The kindly criticism which appeared in your paper on my book "On the Breast" on August 9th contains a statement which perhaps calls for an explanation on my part. Your critic says: "The statement in the preface, however, that no book on the breast has appeared for 20 years is not wholly correct, for a monograph of about the same extent as the present one was published last year and was reviewed in THE LANCET of Oct. 6th, 1923."

He has overlooked another part of my statement which contains the explanation of this seeming inaccuracy; the context is as follows: "It is more than 20 years since the last book on the subject was published in this country by Marmaduke Sheild, and the notice of his death only appeared in the papers when the MS. had already gone to the press. His book remains a mine of information and a monument to his memory." This statement was true when it was written. Marmaduke Sheild died August 4th, 1922, and his obituary notice appeared in THE LANCET on August 19th, and was still fresh in my memory when writing the preface, which thus dates itself to a much earlier period than the appearance of my book.

Unforeseen difficulties in connexion with turning all the illustrations into line drawings delayed the production of the work for more than a year. This accounts for my apparent discourtesy and lack of reference to the excellent monograph of Mr. Willmott Evans, which I am only too glad to have this opportunity of acknowledging, and apologising to him for my seeming rudeness. It is the more necessary to do so as I think your statement has inspired a similar one in the *University College Hospital Magazine.* Here the writer evidently thinks that the second edition of Sampson Handley's work on "Cancer of the Breast" has been referred to and overlooked, but this deals only with cancer of the breast, and is not a book dealing with its general diseases.

I am, Sir, yours faithfully,

DUNCAN C. L. FITZWILLIAMS.

Grosvenor-street, W., August 22nd, 1924.

to have been infected by an unsuspected carrier staying in the house. There was no need for anyone to use the well for drinking purposes as a public supply of pure water was available for the occupants of the house.

An arrangement is in force with the County Nursing Association for the services of a nurse when a district is attacked by measles. Accommodation for the emergency nurse is to be provided through the district medical officer of health. Although measles was more prevalent than in the previous year, Dr. Paget regrets that no district took advantage of this arrangement. No progress has been made during the year in providing for the isolation of ordinary infectious diseases. A conference was held in November to which delegates from all the local sanitary authorities were invited for the purpose of considering the best means of providing small-pox accommodation for every district in the county. The attitude of the county council towards this question will depend upon the outcome of the discussions which ensued. Dr. Paget thinks the shortage of houses is likely to continue while the present prices for building materials are maintained and dilution within the industry in respect of skilled operatives does not take place. Several districts in the county have schemes in operation for the inspection of milch-herds by veterinary surgeons. In the Kettering, Desborough, and Rothwell districts four cows with tuberculous udders were found among 3730. In the Wellingborough district 38 out of 3316 cows were found to have abnormal udders, and in 19 of the 38 the cows were tuberculous. In the Kettering Urban District a scheme is in satisfactory operation by which the butchers give notice of their intention to slaughter in order to facilitate inspection, the individual butchers being protected against loss by an insurance scheme.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 23RD, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 44; scarlet fever, 1275; diphtheria, 623; enteric fever, 81; pneumonia, 390; puerperal fever, 46; cerebro-spinal fever, 5; acute poliomyelitis, 35; acute polio-encephalitis, 1; encephalitis lethargica, 64; continued fever, 1; dysentery, 3; ophthalmia neonatorum, 112. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from enteric fever, 1 from small-pox; 7 from scarlet fever; 29 from diphtheria; 11 from measles; 17 from influenza. In London itself the diphtheria deaths numbered 10. The fatal case of small-pox was reported from Barnsley. Previous fatal cases of small-pox during the quarter were reported, 3 in the week ended July 5th, 1 in the week ended June 28th. The actual number of cases of small-pox reported during the 13 weeks up to and including August 23rd was 336.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the committee 35 cases were considered and £507 10*s.* voted to 34 applicants. The following is a summary of some of the new cases relieved:—

Widow, aged 52, of M.R.C.S. who practised at Westbury and died this year. Late husband's practice has been sold and the payment to be spread over three years. When everything is settled applicant hopes to get an income about £90 per annum. The three children get an income of £13 16*s.* 8*d.* each. Applicant is unable to earn her own living owing to the care of an imbecile daughter aged 26. Voted £20.

Daughter, aged 60, of M.R.C.S. Eng. who practised at Andover and died in 1869. Has had no regular work since 1923 and is now considered too old for the posts she applies for. From 1915 to 1923 was nurse at a rescue maternity home, but on the resignation of the superintendent lost her post owing to the new superintendent bringing her own nurse. Is at present living with a married sister whose husband is a retired clergyman of over 80 years of age with two small pensions and unable to help his sister-in-law. Applicant has been doing knitting, for which she expects to receive 15*s.* She has one month's temporary work in view at 15*s.* a week. Voted £26 in 12 instalments.

Widow, aged 72, of M.D. Irel. who practised at Everton and died in 1894. Applicant left her husband in 1881 through his intemperance and supported herself and son. A few years ago obtained an annuity of £10 from Liverpool Merchants' Guild, which is her only income apart from the money received by knitting, which came to 29*s.* She lives with two unmarried sisters who are not well off. Voted £26 in 12 instalments.

Daughter, aged 37, of L.R.C.P. Edin. who practised in Liverpool and died in 1911. Suffers from epilepsy and is looked after by a sister whose only income is £17 10*s.* a year, the same as the applicant's. Applicant is only able to do temporary light clerical work at times, and the last 12 months only earned £8 10*s.*, and Lady Barr sent £5. Voted £15.

Daughter, aged 82, of M.R.C.S. Eng. who practised in North London and died in 1892. Applicant opened a home of rest for young women and carried it on until 1922 when her health broke down, which compelled her to give up everything. She now lives in one room in her sister's house. Applicant is living on her savings and all she has to depend on is the old age pension, 8*s.* a week, and interest on £100 War Bonds. Voted £10.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., C.B., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: G. E. Hamilton to *Fisgard;* A. R. Davidson to *Resolution;* and J. C. Bringan to *Victory*, for R.N. Barracks, Portsmouth; K. H. Hole to *Frobisher*, and as Squadron Medical Officer, on commg.; and J. O'Flynn to *President*, addl., for three months' hospl. course (on relief).

Surg. Lt.-Comdrs.: T. Gwynne-Jones to *Victory*, for R.N. Barracks; D. P. H. Pearson to *Queen Elizabeth;* A. G. Taylor to R.N. Sick Quarters, Shotley; F. G. Hunt to *Mackay;* L. W. Gemmell to R.N. Hospl., Chatham; R. K. Shaw to *Endeavour;* F. St. B. Wickham to *Assistance;* G. Aubrey to R.N. Hospl., Chatham: A. C. V. Green to *Burslem;* N. B. de M. Greenstreet to *Hermes;* and E. Heffernan to R.N. Hospl., Plymouth.

Surg. Lts.: R. R. Baker to *Iron Duke;* M. Barton to *Adamant;* and J. J. A. O'Sullivan to *Royal Oak;* C. H. Savory to *Victory*, for Portsmouth Dockyard, temp., and to *Frobisher* on commg.; D. Glass to *Wallace;* and J. J. O'Reilly to *Resolution*.

R. Burns to be Surg. Lt.

ROYAL NAVAL VOLUNTEER RESERVE.

Late Temp. Surg. Sub-Lt. A. S. Bradlaw, entered as Proby. Surg. Lt., and attached to the Bristol Division.

Proby. Surg. Sub-Lts. H. O'Connor and R. A. Pallister to *Tiger*, addl., for 28 days' training (appt. to *Cyclops* cancelled).

ROYAL ARMY MEDICAL CORPS.

Maj. A. B. Murray, having attained the age limit, is retd. and retains the rank of Maj. with permission to wear the prescribed uniform.

Maj. A. W. Gater retires on retd. pay and is granted the rank of Lt.-Col.

Temp. Capt. H. C. Beasley and Temp. Capt. T. B. A. Haggard relinquish their commns. and retain the rank of Capt.

The undermentioned Majs. to be Lt.-Cols.: J. Mackenzie, vice Lt.-Col. A. A. Seeds, to retd. pay; N. D. Walker, vice Lt.-Col. F. J. Brakenridge, promoted.

Maj. and Bt. Lt.-Col. H. J. Crossley to be Lt.-Col., vice Lt.-Col. N. J. C. Rutherford, promoted.

Col. C. B. Martin, late R.A.M.C., retires on retd. pay.

Royal Army Medical College: Col. C. W. Mainprise, late R.A.M.C., has been appointed Comdt.

TERRITORIAL ARMY.

General Hospitals: Capt. G. J. Linklater (late R.A.M.C., T.F.) to be Capt.; Lt. G. A. Fisher to be Capt. (Prov.); Lt. C. A. Cowie (late Gordon Highlanders (T.A.)) to be Lt.

Supernumerary for Service with the O.T.C.: Capt. W. E. Le Gros Clark (late R.A.M.C., S.R.) to be Capt.

Capt. W. T. Briscoe to be Maj.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. F. Hawthorn, from Active List, to be Lt.-Col.

INDIAN MEDICAL SERVICE.

Lt.-Col. N. J. C. Rutherford, from R.A.M.C., to be Col., vice Col. C. B. Martin, to ret. pay.

The King has been pleased to give and grant unto Dr. Charles Todd, Technical Expert to the Egyptian Department of Public Health, His Majesty's Royal licence and authority to wear the Insignia of the Second Class of the Order of the Nile, which decoration has been conferred upon him by the King of Egypt in recognition of valuable services rendered by him.

careful treatment, they also apply it to cases with quite extensive disease. It is in this latter type that, in our experience, adhesions are so commonly found, and interfere with or entirely prevent collapse of the affected portion of lung.

In the small number of cases under the care of Dr. Clive Riviere to whom this treatment was applied, all had considerable disease of one lung and sufficient in the other to preclude complete collapse of the more affected lung. In these cases adhesions caused considerable difficulty, and we should be interested to know in what percentage of Barlow and Kramer's cases the same complications occurred. We cannot agree with them that there is little or no general disturbance during treatment, as nearly all our cases showed febrile reactions, a point to which we have referred in a paper on Artificial Pneumothorax, to be published shortly.

The X ray photos of these cases are not always easy to interpret owing to the fact that if the pocket of air is confined to the anterior surface of the lung, at no place on the skiagram is there an absence of lung detail indicating the presence of a pneumothorax. The X ray photos of Dr. Wingfield's cases, though not very convincing at first sight, are more intelligible if this point is borne in mind, and would, no doubt, be quite conclusive if stereoscopic pictures had been taken.

We are, Sir, yours faithfully,
F. BEDO HOBBS, M.B., M.R.C.P., D.P.H.
A. I. G. MCLAUGHLIN, M.B., Ch.M.

August 21st, 1924.

IS LYMPHATIC OBSTRUCTION A FACTOR IN SPRUE?

To the Editor of THE LANCET.

SIR,—Recently two cases have come under my care which may possibly throw some light upon the pathology of sprue, a disease the pathology of which is still obscure. In both these cases laparotomy was performed for chronic appendicitis, and it was observed that there were certain changes in the small intestine and the lacteals. Dr. P. H. Manson-Bahr, in his interesting article in your issue of June 7th last, calls attention to the importance of post-mortem examinations in the earlier stages of the disease. Such opportunities are of comparatively rare occurrence. In addition, there is the possibility of observation during laparotomy performed for surgical complaints. The following are instances of the latter:—

1. Mrs. H. was operated upon for chronic appendicitis on April 30th, 1924. She gave a history of sprue two years previously, and stated that though better she still had loose stools. At the operation, noticing that the ileum was thinned and of different colour from normal, I pulled down a piece of jejunum and found a very striking condition. All the lacteal vessels stood out in a most remarkable manner, each group of blood-vessels being accompanied by a white knotted cord, which could be traced across the surface of the intestine back into the mesentery for some distance. It gave the appearance of a piece of thick cotton having been inserted along the course of all the vessels with knots tied at regular intervals. This condition was uniform throughout the few coils of intestine which I examined. The intestinal wall was of a dull brownish mottled appearance, darker brown areas merging into areas of a lighter shade. During convalescence the stools were not typical of sprue but loose and pale.

2. Mrs. S. On May 28th, 1924, I had the opportunity of verifying the above observations in a case of definitely active sprue with characteristic stools, operation being performed for chronic appendicitis. I found a very similar condition of the intestine and lacteals. In addition, the mesenteric glands were seen to be swollen. The lacteals on closer examination were found to collapse on pressure with the point of the needle and did not appear to be thickened as far as one could make out. In neither case did I find anything indicative of ulceration of the small intestine. However, with a small appendix incision one's opportunity for a thorough exploration was necessarily restricted.

Never having seen the above-noted appearances before during a considerable experience of abdominal surgery, I cannot think there is any doubt that these are manifestations of sprue. Moreover, a distended condition of the lacteals, as a physiological state, is far from probable after a period of starvation preparatory to operation. Two facts would appear to be possible to infer from a condition of distended lacteals: Firstly, that absorption is taking place from the mucous membrane of the small intestine; and, secondly, that there is a delay in the passage of chyle to the general system. The point arises as to where the delay occurs, and I would suggest the lymphatic glands of the mesentery as the most probable. In the case of Mrs. S., these glands were certainly enlarged. We know positively that the mucous membrane of the small intestine in the final stages of sprue becomes so profoundly changed that its power of absorbing is little or nil. In the period of active disease is the deficiency in absorption accounted for by a defect in the small intestine mucous membrane, obstruction in the lymphatic system, or by both?

Lymphatic obstruction may possibly be the predominant factor. As an hypothesis it is quite conceivable that the continued passage of toxin from the intestine may inflame and finally sclerose the lymph glands of the mesentery, hindering and finally blocking out the lymph passage way.

After all, what other chronic disease have we in the whole sphere of medicine in which large areas, if not the whole, of the small intestine mucous membrane is inflamed, evidenced by the destruction of the intestinal wall seen at autopsies as the most conspicuous lesion? The conception of concurrent changes in the mesenteric glands caused by their efforts to deal with noxious substances derived from the small intestine is quite within the range of possibility, and it should be remembered this may be going on from end to end of the small intestine. The putting out of action of small groups of mesenteric glands is well known in several diseases, but what disease except sprue puts such a heavy strain on the mesenteric glands as a whole?

Whatever the explanation of the peculiar appearances which I have described, I feel that they are of sufficient importance to record in the hope that surgeons and pathologists will pay particular attention to the lymphatic system when suitable opportunities arise.—I am, Sir, yours faithfully,

I. DAVENPORT JONES, M.D. Lond.,
Lieut.-Col., I.M.S.

Bombay, August 3rd, 1924.

INTOLERANCE TO A DENTURE.

To the Editor of THE LANCET.

SIR,—I have only just seen Dr. H. St. Arnaud Agate's request for advice on this condition in your issue of August 9th. I recently had a similar case under my care, a neurasthenic who had been under treatment in an officers' pensions hospital, where all his teeth had been extracted, presumably because they were carious. He had then been fitted with the lightest and most perfectly fitting dentures I had ever seen. These he had carried about for nearly two years, but he had never been able to wear them for longer than two minutes owing to invariable retching and vomiting. He told me that he had had the dentures in and out as many as a hundred times an hour. I swabbed his mouth thoroughly with a 10 per cent. solution of novocaine, and first fitted the lower denture. He retained this easily, so after 15 minutes I repeated the swabbing and applied the upper denture. He retched two or three times, but aided by a sharp command to "stick it," he succeeded in keeping the complete set in position. He left my room smoking a cigarette after 15 minutes' chatting, went home, had a hearty meal, and has worn the dentures ever since without trouble.

This method ought to succeed in Dr. Agate's case, as apparently the same neurasthenic element predominates as in my case.

I am, Sir, yours faithfully,
W. ARTHUR JACKSON, M.D.

Marple, Cheshire, August 25th, 1924.

THE DIAGNOSIS OF PERNICIOUS ANÆMIA.

To the Editor of THE LANCET.

SIR,—There is an ingenious trick, due I believe originally to the late Prof. S. G. Shattock, for getting a comparative view of the size of red cells which is available to those who are not prepared to face the complications of Dr. A. Pijper's apparatus (THE LANCET, August 23rd, p. 367) or the labour of Dr. C. Price-Jones's exact measurements. The blood film of the patient is made on a slide in the ordinary way, and one of one's own blood on a cover-glass; both are stained and dried and then mounted with balsam in contact with one another. The two layers of red corpuscles are quite distinct from one another, but a small turn of the fine adjustment brings them into view successively so quickly that it is easy to see whether there is any striking difference in size.

I am, Sir, yours faithfully,
A. E. BOYCOTT.
University College Hospital Medical School,
August 26th, 1924.

STAFF PAYMENT AT THE BRITISH DENTISTS' HOSPITAL.

To the Editor of THE LANCET.

SIR,—I wish to thank you for the comprehensive report [1] you have made of the work being done by this hospital. It is, however, misleading to state simply that the dentists act in a purely honorary capacity. The work of the hospital divides into several branches. First, that of a public dental service open to all but those who are able to pay dentists' ordinary fees. For this work the dentists give their services voluntarily, receiving only out-of-pocket expenses for dentures and the like. Secondly, the maternity and child welfare and tuberculosis centres are worked by dentists who are appointed by the hospital under the local medical officer of health and are paid the usual fee per session. Thirdly, the L.C.C. dental clinic at which dentists appointed by the hospital with the approval of the L.C.C. are paid by the hospital at the usual rate.

The remarks of Sir Harry Baldwin at the annual meeting were intended to apply to the hospital work only as carried on by the voluntary staff. Patients pay fees according to their means and these fees go toward the maintenance of the hospital. If they are able to pay above a maximum they are referred to local dentists.

I am, Sir, yours faithfully,
GEORGE THOMSON,
Chairman, Executive Committee.
31, Camden-road, N.W. 1, August 28th, 1924.

THE CLINICAL THERMOMETER AS A CARRIER OF INFECTION.

To the Editor of THE LANCET.

SIR,—I was interested to read Major H. C. Brown's letter on this subject. It has always seemed to me that the clinical thermometer, if insufficiently sterilised, is a very active carrier of infection. In hospitals I have seen it conveyed from the mouth of one patient to that of another after a few minutes immersion in a solution of about 1 in 60 of carbolic acid. By this immersion the thermometer was supposed to be sterilised. That such sterilisation is useless goes without saying. I agree that washing with water is also ineffective.

For many years I have always carried my thermometer in a special case. This case is solidly made and has a very long thread on it, so that leakage is impossible. In the case is either methylated spirit or absolute alcohol. After using the thermometer I wash it well and then return it to the case. By adopting this method I believe the chances of carrying infection on the thermometer are very small indeed. I get special 2½ inch thermometers, with a magnifying lens, and the case is 3 inches long only, so that it cannot be called cumbersome. Various instrument makers supply these cases; the one I have, some 12 years old, happens to be stamped with the name of Maw. Doubtless this firm still supplies the same case.

It is not necessary to renew the spirit more than about once a week. I believe the method is thoroughly effective, and is certainly very little trouble. I do not think there is any doubt that hypodermic syringes can be kept sterile in a case containing absolute alcohol; I do not see why the same method should not be as efficacious with thermometers.

I am, Sir, yours faithfully,
A. GRAHAM-STEWART, M.B., Ch.B.
Margate, August 22nd, 1924.

SELECTIVE COLLAPSE IN ARTIFICIAL PNEUMOTHORAX.

To the Editor of THE LANCET.

SIR,—Dr. R. C. Wingfield's letter, under this title, in your issue of August 16th bears witness to the important practical results which may follow from recognition of the principle expressed in the words "if small quantities of air are introduced into a free pleural cavity containing a lung only partially infiltrated with tuberculosis, the air so introduced will tend to collect over or round the diseased areas only, collapsing these, and leaving the rest of the lung expanded and capable of function."

He gives the credit for demonstrating this selective localisation of the air in the pleura to the American workers, Barlow and Kramer.[1] As a matter of fact, Dr. Parry Morgan, working in this laboratory during 1911–13, was the first (so far as I am aware) to show that such a localisation must occur, since the presence of a relatively inelastic tuberculous focus in the lung creates a condition of increased tension along an axis passing from the root of the lung, through the focus, to the chest wall. In his paper on the Possibility of Achieving by Partial Pneumothorax the Advantages of Complete Pneumothorax[2] Dr. Parry Morgan stated this view very clearly; he also described an experiment which served to demonstrate that such a localisation did actually occur, and went on to advocate the induction of partial pneumothorax, if necessary on both sides of the chest simultaneously.

Unfortunately the outbreak of war interfered with the continuance of his work and the reporting of cases treated on these lines, but a brief reference to the latter will be found in the *Quarterly Journal of Medicine* for 1917, vol. ii., p. 1.

I am, Sir, yours faithfully,
LEONARD COLEBROOK.
Inoculation Department, St. Mary's Hospital,
Paddington, W., August 22nd, 1924.

To the Editor of THE LANCET.

SIR,—Dr. Wingfield states that no great interest has been aroused by the report of Nathan Barlow and David Kramer, published in the *American Review of Tuberculosis* (April, 1922), regarding selective collapse in artificial pneumothorax. We entirely agree with him that this modification of artificial pneumothorax treatment opens up great possibilities and certainly requires fuller investigation. At the City of London Hospital for Diseases of the Heart and Lungs a few cases have been treated on the lines that Barlow and Kramer suggest, not, however, with quite the same degree of success as they would seem to indicate. In addition to recommending this form of treatment for incipient and early cases which are making no progress in spite of next English physiologist to receive it was Bayliss. The award was the testimony of the scientific world of its appreciation of the sterling work of some 40 years which culminated as regards its outward and visible signs in the publication of the "Principles of General Physiology." It was by the "Principles" that the world which was not lucky enough to be in personal contact with him learned that he was really a great man. Since the first publication of "Foster's Text-Book" there had been no outstanding book in English till the "Principles" came and showed us what Bayliss thought physiology was about; both books stand out because they are impressed with the personality of the authors and they are valued because of that personal character, as well as for the learning that they represent. The biologist may complain that much that might reasonably be called general physiology finds no place in its pages. But the author is less concerned with the characteristics of life than with the mechanisms through which they are manifested; his object, as he says, is to discuss the physical and clinical processes which intervene in the phenomena of life. But this is because it is only to these processes that it is possible to apply the experimental method with profit, and whatever the book includes and whatever it omits, as a matter of experience one finds it in use by physiologists, pathologists, zoologists, botanists, and even chemists, who dig in it, and will continue to dig in it, fruitfully for the sake of the Bayliss which they find there.

---

[1] THE LANCET, August 16th, p. 333.

[1] American Review of Tuberculosis, April, 1922.

[2] THE LANCET, 1913, ii., 18.

Sir E. Sharpey Schafer writes:—

"I have known Bayliss intimately for more than 40 years, his early research on vaso-dilator nerves and the one, with Rose Bradford, on the electromotive changes in the salivary glands having been conducted in the old physiological laboratory at University College in the 'eighties. From the very first his experiments were characterised by the care with which they were thought out and the accuracy with which they were performed. His apparatus was never elaborate, but, with Faraday, he knew how to obtain important results by simple means. The single desire to arrive at the truth, without any idea of personal achievement, has furnished the keynote of his career. Not only is his work remarkable for the number and variety of its contributions to physiological knowledge, but still more for the breadth of view which marks its exposition. This feature eventually culminated in his monumental work on "General Physiology," which, more than any other publication in any language, has contributed towards laying a sure foundation of physiology in all its modern developments; every branch of the subject—histology, physics, chemistry, and most of all physical chemistry—having been called upon to contribute its quota.

"Regarding his personal characteristics it is impossible to speak too warmly. The cheerfulness and geniality of his disposition endeared him to his friends; and since these comprise most of his physiological colleagues in all parts of the world, it is certain that no presence will be more missed at future gatherings of physiologists than that of Sir William Bayliss."

Bayliss was knighted in 1922. He received honours also from many foreign academies and from universities and learned societies at home and became an honorary Fellow of his old college, Wadham. He could write after his name M.A., D.Sc. Oxf., hon. LL.D. Aberd. and St. And., hon. Sc.D. Dub. He was chairman and member of numerous committees, treasurer of the Physiological Society, and in 1923 accepted the post of editor of *Physiological Abstracts*. But from first to last he was a student. He escaped the administrative entanglements of the modern university professor and gave himself whole-heartedly to the pursuit of knowledge; he proved all things and held fast that which was good. At any rate for elementary students he was an indifferent expositor and it was not very easy to get him to interest himself seriously in anything but his own problems—which is apt to be a characteristic of the investigators who find things out. But all who were in contact with him knew that there came from him something more than a charming friendliness and sympathy and an amazing wealth of knowledge—something by way of ideal inspiration and point of view which represents university teaching at its highest.

He married in 1893 Gertrude Starling, sister of his friend and fellow worker, and had three sons and one daughter.

WILLIAM AUGUSTUS MAYBURY,

M.D., M.CH. R.U.I.

THE recent death at his residence, West Stockwell-street, Colchester, of Dr. William Augustus Maybury, aged 77, second son of the late William Augustus Maybury, surgeon, of Frimley, Surrey, removes one of the best known of Colchester's medical practitioners. Possessed of remarkable vitality for his age, he retained his faculties and interest in affairs to the end. Dr. Maybury held a record which must be unique for a local doctor. He was in practice in the borough for half a century, was churchwarden of St. Martin's for nearly that period, was the borough police surgeon for over 40 years, and held an appointment as medical officer in the Colchester Union from 1876 until ten days before his death. Educated at the City of London School, he started his medical career at St. Thomas's, qualifying as M.R.C.S. Eng. in 1870 and as L.S.A. in the following year. In 1871 he also graduated M.D. at the Queen's University, Ireland. His first appointment was as house surgeon to St. Thomas's Hospital, followed by the post of resident medical officer to the Newark Hospital. Dr. Maybury will be remembered by many for his cheerful and kindly disposition. As a witness in his capacity of police surgeon he was one of the most precise and painstaking of doctors. His evidence, which always carried weight, was scarcely ever called into question.

Thomas Sydney Short, M.D. Lond., D.P H. Camb., senior physician to the General Hospital, Birmingham, died recently from a seizure at Claverdon, Warwick, while on holiday.

THE LATE DR. E. S. PATTISON.—Edward Seton Pattison, M.R.C.S. Eng., L.R.C.P. Edin., who died on August 27th in Charing Cross Hospital, London, at the age of 69, was at one time medical officer of the St. Mark's Training College, Chelsea, and was divisional surgeon to the Metropolitan Police. Dr. Pattison studied medicine at Charing Cross Hospital and qualified in 1879. As a student he acted as surgeon to the British National Aid Society in Bulgaria and Rumania during the Turko-Russian War of 1877–78, and received the Second Class of the Star of Rumania.

THE LATE DR. J. LASCELLES.—John Lascelles, M.B., Ch.B. (Hons.) Belf., who died suddenly of heart failure at his residence at Earlestown, Lancs, on August 16th, was born in 1892 in Downpatrick, Co. Down, Ireland. He received his medical education at Queen's University, Belfast, where he won scholarships in the Second and Third Medical Examinations, and a special exhibition in surgery in the Final Examination. Qualifying in 1917 he joined the R.A.M.C. as Lieutenant, and, after service in East Africa and Constantinople, was promoted Captain. On demobilisation he took up general practice in Earlestown, where he remained until his death. Dr. Lascelles married a daughter of the late Dr. Archibald Wallace of Rochdale in 1921.

DR. E. H. LIPSCOMB.—A tragedy at sea has deprived the medical profession of a well-known member in the person of Dr. Eustace H. Lipscomb. Dr. Lipscomb, with his sister-in-law and his two children, was sailing with a boatman round a harbour off the coast of Brittany, when the boat capsized, with the result that Dr. Lipscomb and his sister-in-law were drowned, the children being fortunately saved by a passing fishing-boat. Dr. Lipscomb, who was 64 years of age, was educated at Norwich Grammar School, Caius College, Cambridge, and Guy's Hospital, and spent most of his professional life at St. Albans. Here he was equally well known as a doctor and in the public life of the city, and served as mayor, a position which had been previously occupied by both his father and his grandfather. The accident occurred on August 26th.

UNIVERSAL ANÆSTHETIC APPARATUS.

To the Editor of THE LANCET.

SIR,—Mr. Langton Hewer is to be congratulated on the comprehensive apparatus he has produced, as described in your issue of August 16th. It is, I am sure, a step in the right direction—i.e., that of producing a universally applicable anæsthetic apparatus. From the block, however, the machine appears unduly complicated, and, as is usually the case, liberally festooned with rubber tubing. It has always seemed unfortunate to me that machines of this sort, which show a fairly high degree of mechanical complication, are not produced with permanent connexions which do not admit of mis-union and do not perish. I also welcome Mr. Hewer's concession to the views of the majority as regards anæsthetic agents, as indicated in para. (4) of his letter.

I am, Sir, yours faithfully,
R. J. CLAUSEN, M.B.

Carlton-hill, N.W., August 25th, 1924.

PLAGUE AND THE TARABAGAN.

To the Editor of THE LANCET.

SIR,—In your annotation entitled An Arraignment of the Bobac (THE LANCET, August 16th, p. 330) I note that you speak of Dr. M. T. Schreiber, whose article was published in 1907, as "an early writer" on the subject of plague and the tarabagan (*Arctomys bobac*). May I point out that Russian medical observers had written on this question many years earlier. In an article published in the *Journal of Tropical Medicine* of February, 1900, I quoted at some length all the information then available upon this question, from Russian and other sources. I there showed that, in the province of Transbaikalia, outbreaks of tarabagan plague had occurred at least as far back as 1881; and that, in Eastern Mongolia, similar outbreaks had recurred almost every year since 1888. I have since recorded, in your columns and elsewhere, many other outbreaks. The most authoritative Russian writers on the subject are Drs. Biélavski and Riéshetnikof, who published a detailed report on their observations in a Russian journal in April, 1895, and Dr. Zabolotny, who gave much highly interesting information on the subject in the discussions in the last International Sanitary Conference (Paris, 1911).

Your statement that "previous observations upon the tarabagan have been made rather by native hunters than by trained medical men," though probably literally true as regards the number of observations, is perhaps a little misleading. Russian observers have most carefully studied the whole matter; have demonstrated, at least 13 years ago, that the disease in the marmot is true plague; that it is caused by the same bacillus as human plague; that it is transmitted from animal to animal and from animal to man by fleas; and that the tarabagan disease was the source and origin of the truly terrifying epidemic of pneumonic plague in Manchuria in 1911.

Dr. Teh's report, on which your annotation is based, would seem only to confirm (save in the matter of transmission by fleas) the conclusions arrived at by Dr. Zabolotny and other Russian observers as far back as 1911.

I am, Sir, yours faithfully,
Ealing, August 18th, 1924. F. G. CLEMOW, M.D.

*** We should regret any slight upon the work done by trained Russian medical observers on the subject of the tarabagan plague. As British Delegate to the Constantinople Board of Health, Dr. Clemow kept us for many years closely in touch with outbreaks of tarabagan plague reported in Russian journals and archives. Reference to the summaries given in our issues of 1905, ii., 1731; 1909, i., 1863; 1911, ii., 786; and 1913, i., 1698, amongst others, will show how nearly Russian observers came to a final conclusion.—ED. L.

Obituary.

SIR WILLIAM MADDOCK BAYLISS, F.R.S.

BY the death of Sir William Bayliss on August 27th there has passed away one of the greatest physiologists of modern times. William Maddock Bayliss was born at Wolverhampton in 1860. He was the only son of Moses Bayliss, an iron manufacturer, and received his education privately as he was of delicate constitution. He first entered his father's business, but not finding the commercial world congenial he decided to take up the study of medicine. He thus became apprenticed to a doctor in the old style and learned dressing and dispensing in the local hospital. In 1881, at the age of 21, he came to London and entered as a student at University College, where he came under the influence of two great biologists, Ray Lankester and Burdon-Sanderson. The following year he obtained the University Scholarship in Zoology and took the degree of B.Sc. He then began the study of physiology under Burdon-Sanderson, and, in 1883, when Burdon-Sanderson was transferred to Oxford, Bayliss continued his studies under Schafer, but he was not destined to advance any further in the medical curriculum. The subject of anatomy proved a dull one to him, and, having failed in this subject in the second M.B. examination, he gave up the idea of a medical qualification and turned his attention to physiology alone. This decision was, no doubt, taken under the profound impression Burdon-Sanderson and his work had made upon the young student, and in October, 1885, Bayliss followed Burdon-Sanderson to Oxford and entered Wadham College. Three years later he took a first class in the final School of Natural Science in Physiology. The circumstances of Bayliss's student life were destined to shape to no small extent his later activities. His experience of medical practice as a doctor's apprentice in Wolverhampton was of value to him later in enabling him to grasp the true value of medical problems and to perceive the practical application of physiology to these problems, and during his studies at Oxford, at an age senior to that of the average undergraduate, he acquired a breadth of outlook in matters philosophical which later distinguished him among his compeers. Having taken his degree, he returned to London and began work again under Schafer at University College. In the early part of 1890 E. H. Starling joined forces with him in the laboratory of University College, and thus was begun a scientific partnership which endured until Bayliss's death. In conjunction with Starling he did pioneer work on the electro-motive phenomena accompanying the heart beat, the arrangement of vaso-motor fibres in the sympathetic, the innervation of the intestine, the action of an extract of intestinal mucosa in stimulating the pancreas to secrete the osmotic pressure of colloids, the reaction of the blood, and a number of other physiological topics.

In 1893 Bayliss published a paper, which has since become classical, on the depressor nerves, and later, between 1901 and 1908, he wrote a series of papers on vasodilator nerves, their origin and mode of action. When in 1899 Starling was appointed to the Jodrell Chair of Physiology at University College in succession to Schafer, Bayliss acted as his assistant, and took an active part in the teaching of the department, finally becoming professor of general physiology in 1912. From 1904 onwards he produced a long series of papers in the *Journal of Physiology* and elsewhere, and his monograph on the nature of enzyme action, published in 1908, has since gone through four editions. In 1914 appeared the "Principles of General Physiology," and in 1919 Bayliss received the Copley Medal of the Royal Society. The Copley Medal is awarded to the living author of such philosophical research as may appear to be deserving of that honour. It was given to Stephen Hales, the curate of Teddington, who first measured blood pressure, in 1739, and the

North Walsham War Memorial Cottage Hospital.—On August 27th the cottage hospital raised by the town and district of North Walsham as a memorial to the 179 men from the locality who fell in the late war was opened by Her Highness Princess Marie Louise. The total sum subscribed to build, equip, and endow the memorial amounted to £8700, and the hospital was opened practically free from debt. Sir Hamilton Ballance, hon. consulting surgeon to the new institution, referred at the opening ceremony to the need of an X ray installation for minor work in every cottage hospital, and hoped it would not be long before North Walsham had the necessary apparatus.

Bolingbroke Hospital, Wandsworth Common, S.W.—The sum of £10,000 has been given to this hospital by Sir James and Lady Carmichael, of Kingston Hill Place, Kingston, towards the cost of erecting the William Shepherd memorial wing. The cost of this wing, when fully equipped, will amount to £60,000.

Appointments.

Dickson, W. M., M.B. Ch.B., F.R.C.S. Eng., has been appointed Surgeon to Out-patients, Willesden General Hospital.

Hart, E. R., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Hertford District of the County of Hertford.

Neilson, J. P., M.B., Ch.B. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Llansawel District of the County of Carmarthen.

Tuohy, P. G., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Uckfield District of the County of Sussex.

Westminster Hospital Medical School: **Wilson, J. G.**, M.B., B.S., M.R.C.S., L.R.C.P., D.P.H. R.C.P.S. Eng., House Physician and Resident Medical Officer: **Coles, B. A.**, B.Sc. Wales, M.R.C.S., L.R.C.P., Resident Obstetric Assistant; **Williams, D.**, M.R.C.S., L.R.C.P., **Harris, I.**, M.R.C.S., L.R.C.P., House Physicians: **Poole, E. B.** M.R.C.S., L.R.C.P., **Bennion, E. R.**, **Zimmerman, M.**, M.R.C.S., L.R.C.P., House Surgeons; **Davies, M.**, M.R.C.S., L.R.C.P., Assistant House Physician: **Davies, J.**, M.R.C.S., L.R.C.P., Assistant House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, District Infirmary and Children's Hospital.—Hon. M.O. for Electro-Therapeutic Dept.

Barnsley County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Birmingham General Dispensary.—M.O. £550.

Bootle Borough Hospital.—Sen. M.O., also two Jun. M.O.'s. £150 and £125 respectively.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £120.

Bristol, Cossham Memorial Hospital, Kingswood.—H.S. £150.

Carshalton, Queen Mary's Hospital for Children.—Asst. M.O. £500.

Chester Royal Infirmary.—Asst. H.S. £150.

Coventry and Warwickshire Hospital.—Vacancy on Hon. Surg. Staff.

Dover, Royal Victoria Hospital.—H.S. £180.

Exeter, Royal Devon and Exeter Hospital.—H.P. £150.

Gloucestershire Royal Infirmary, Gloucester.—Asst. P. and Pathologist.

Halifax Royal Infirmary.—Third H.S. £150.

Leeds Public Dispensary.—Jun. Res. M.O. £150.

Maidstone, West Kent General Hospital.—Two H.S.'s. Each £220.

Manchester Education Committee.—Asst. Sch. M.O. £600.

Manchester University.—Asst. Lecturer in Chemical Pathology. £300–£500.

Middlesex Hospital and Medical School, W.—Surg. Reg. £300.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—M.O. for Out-patients. £125.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—H.P.'s and H.S.'s. Each £50.

Northampton County Mental Hospital, Berrywood.—Jun. Asst. M.O. £350.

Northampton General Hospital.—Hon. P.

Norwich, Norfolk and Norwich Hospital.—Cas. O. and H.S. £150.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s, H.P. Each £150. Also Jun. H.S. and H.P. Each £110.

Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Two H.S.'s. Each £150.

Royal Naval Medical Service.—Surg. Lieuts. 25s. per day.

Royal Northern Hospital, Holloway, N.—H.S. £75.

St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C.—H.S. £75.

Salford Union Infirmary, Hope, Pendleton, near Manchester.—Third Asst. Res. M.O. £275.

Scarborough Hospital and Dispensary.—H.S. £150.

Sheffield Royal Hospital.—Res. Surg. O. £200.

Sheffield Royal Infirmary.—Res. Surg. O. £200.

Sunderland Royal Infirmary.—Two H.S.'s. Each £140.

West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each £100.

Worksop Union Workhouse, &c.—M.O. £230.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments at Cwmbran, Monmouth, and Eyam, Derby.

The Secretary of State for the Home Department gives notice that, in consequence of the resignation of Dr. Clement Dukes, one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Districts of the Rugby and Daventry County Courts (Circuit No. 23), a fresh appointment has to be made. Applications should be addressed to the Private Secretary, Home Office, and should reach him not later than Sept. 20th, 1924.

Births, Marriages, and Deaths.

BIRTHS.

Allen.—On August 27th, at a nursing home, Highgate, the wife of Francis Allen, M.B., of a son.

Hitchings.—On August 26th, at Westfield, Hawkhurst, Kent, the wife of Dr. D. B. Hitchings, of a son.

Murphy.—On August 26th, at "Stonefield," Kidbrook-grove, Blackheath, the wife of Denis V. Murphy, M.B., of a daughter.

Rope.—On August 20th, the wife of Dr. A. D. Rope, of Quarry-place, Shrewsbury, of a son.

Thomas.—On August 28th, at Clapham, London, to Dorothy (Dorothy S. Chamberlain, M.B., B.S. Lond.), wife of Cyril J. Thomas, M.R.C.S., L.R.C.P., of the County Mental Hospital, Lancaster—a son.

MARRIAGES.

Burton—Freir.—On August 28th, at Pinchbeck Parish Church, by special licence, Wilfred Robert Burton, L.R.C.P.I. and L.M., L.R.C.S.I., to Ethel, daughter of Mr. and Mrs. S. Freir, of Yew Tree House, Sharpe's Bridge, Spalding.

Campbell—Chrimes.—On August 28th, at Nevin, Carnarvonshire, John Maurice Hardman Campbell, O.B.E., M.D., of Oxford, to Ethel Mary, second daughter of Captain Chrimes, C.B.E., and Mrs. Chrimes, of Gresford.

DEATHS.

Bayliss.—On August 27th, at St. Cuthberts, Hampstead Heath, Sir William Maddock Bayliss, M.A., D.Sc., F.R.S., Professor of General Physiology at University College, London, aged 64.

Dempster.—On August 28th, William Thomas Dempster, M.B.E., M.R.C.S. Eng., L.R.C.P. Lond., of Brighton-road, Croydon.

Gamble.—On August 23rd, at Glen Maize, Donnybrook, Natal, Leonard Dobbin Gamble, M.B., C.M. Edin., late of Abergavenny, Mon.

Lipscomb.—On August 25th, at Trégastel, Brittany, the result of a boating accident, Eustace Henry Lipscomb, M.B., B.C. Cantab., J.P., of Holywell Hill, St. Albans, Herts, aged 64.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—As the result of recent examinations the following candidates passed in the undermentioned subjects :—

Surgery.—M. Bannounah, Guy's Hosp.; E. H. Boodrie, St. Mary's Hosp.; J. Crawford, Royal Free Hosp.; F. M. Deighton, Univ. Coll. Hosp.; C. S. Forrest, Manchester and Middlesex Hosp.; J. W. Graham, Manchester; J. C. C. Langford, Manchester and St. Bart.'s Hosp.; Z. Roodyn, Middlesex Hosp.; and C. W. Warne, Guy's Hosp.

Medicine.—F. M. Deighton, Univ. Coll. Hosp.; J. W. Graham, Manchester; G. L. W. Iredale, Edinburgh and St. Mary's Hosp.; W. R. S. Jaecques, Ghent: A. J. Moody and H. Morris (Sect. II.), St. Bart.'s Hosp.; W. E. Pennington, Liverpool; Z. Roodyn, Middlesex Hosp.; and J. G. E. Vachell, St. George's Hosp.

Forensic Medicine.—H. L. Bernstein, Guy's Hosp.; A. K. A. Carter and F. M. Deighton, Univ. Coll. Hosp.; R. C. Glover, Leeds; J. W. Graham, Manchester; A. J. Moody, St. Bart.'s Hosp.; W. E. Pennington, Liverpool; B. A. Perott, Petrograd; M. Schwartzman, Odessa; and Z. Roodyn, Middlesex Hosp.

Midwifery.—W. Bentley, Birmingham; F. M. Deighton, Univ. Coll. Hosp.; J. W. Graham, Manchester; J. C. C. Langford, Manchester and St. Bart.'s Hosp.; E. J. P. McDowell, St. Thomas's Hosp.; W. E. Pennington, Liverpool: and Z. Roodyn, Middlesex Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: J. Crawford, F. M. Deighton, J. W. Graham, G. L. W. Iredale, J. C. C. Langford, H. Morris, Z. Roodyn, and J. G. E. Vachell.

DIPLOMA OF LARYNGOLOGY AND OTOLOGY OF THE CONJOINT COLLEGES.—In the article upon Special Diplomas in the Students' Number of THE LANCET, published last week, there was an omission to mention the special Diploma in Laryngology and Otology granted by the English Conjoint Board (D.L.O.). This Diploma was instituted in 1923, and the conditions for obtaining it follow the accepted pattern. Candidates must possess a registrable qualification, and will be examined in the anatomy, physiology, medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea, bronchi, and œsophagus. The examination takes place twice yearly, and notice of entry, with fee of £6 6s., should be sent 14 days previously to the Secretary, Examination Hall, Queen-square, London, W.C. 1.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Sept. 8th a three weeks' course in ophthalmology commences at the Royal Westminster Ophthalmic Hospital. Clinical instruction will be given every afternoon from 2 o'clock and special demonstrations three times a week on methods of examination, fundus class, and common affections of the eye. A fortnight's course has been arranged at the Infants Hospital from Sept. 15th to 27th. The syllabus deals with diseases of infants from various aspects and consists of clinical demonstrations, "round table" consultations, lectures, &c. Three visits of inspection are to be made: To St. Margaret's Hospital for Ophthalmia Neonatorum, Thavies Inn (Holborn), and the Nursery Training School (Golders Green). A fortnight's intensive course in medicine, surgery, and the various special departments will be held at the Westminster Hospital from Sept. 22nd to Oct. 4th, of which further particulars will be shortly published. Dr. Porter Phillips and Dr. Thomas Beaton will give a series of lecture-demonstrations on Tuesdays and Saturdays, at 11 A.M., in psychological medicine at the Bethlem Royal Hospital from Sept. 30th to Oct. 25th. Courses arranged for October are: Diseases of children, diseases of the ear, nose, and throat, electrotherapy, tropical medicine, urology, and a fortnight's intensive in medicine and surgery and other departments. Full particulars can be obtained from the Secretary of the Association, 1, Wimpole-street, W. 1.

UNIVERSITY COLLEGE HOSPITAL, LONDON.—The annual dinner of the past and present students of University College Hospital will be held at the Hotel Cecil on Friday, Oct. 3rd, at 7.30 P.M. Dr. Michael Foster, O.B.E., will be in the chair. Tickets can be obtained from the secretaries, Mr. Gwynne Williams and Prof. T. R. Elliott, University College Hospital Medical School.

DONATIONS AND BEQUESTS.—By will the late Mr. Richard Stanley Varley, after certain minor bequests, left the residue of his property, about £20,000, to his brother Gilbert with the request, but without creating any trust in the matter, that if circumstances hereafter should permit, there should be paid £2000 to Magdalen College, Oxford, for the Alec Varley Fund, and the balance of the residue to the Vice-Chancellor of the University of Oxford, for the advancement of science, and in particular for medical research.

CUMBERLAND INFIRMARY, CARLISLE.—A gift of £1500 has been received by this infirmary from Mr. P. H. Holt, High Sheriff of Cumberland, for the purpose of establishing a pathological laboratory at the institution. At a recent quarterly meeting of the governors Dr. N. Maclaren said that the need for such a laboratory had been felt by the staff for a long time, and its provision would mark a new era in the life and utility of the Cumberland Infirmary.

KING EDWARD'S HOSPITAL FUND FOR LONDON: KING'S COLLEGE HOSPITAL.—In accordance with the decision of the Fund to apply the legacies of the late Mr. and Mrs. John Wells, estimated at over £200,000, to extensions, improvements, and other special needs of hospitals, a grant has been made to enable 14 additional beds for accident cases to be opened at King's College Hospital. The need for additional accommodation for accident cases was emphasised in the report, issued last spring, of a special committee of the Fund.

BRIGHTON AND ROSE DAY.—The allocation has just been made of the proceeds of Alexandra Day in Brighton and district, which amounted to £750. The distribution was as follows:—Royal Sussex County Hospital, £275; Royal Alexandra Hospital for Sick Children and the Sussex Maternity and Women's Hospital, each £73; Brighton and Hove Dispensary, £80; Lady Chichester Hospital and the new Sussex Hospital, each £48; Eye Hospital and Queen's Nurses, each £31 10*s.*; Surgical Aid Society, £22; and the Brighton Dental Hospital and the Clayton and Keymer Nursing Association, each £10.

MANCHESTER ROYAL EYE HOSPITAL.—The annual report for 1923 states that 30,502 out-patients and 2045 in-patients were treated; the average length of stay in the hospital of the in-patients was 19·1 days. The number of accidents treated was 8497, an average of 23·3 per day. The income from all sources was £18,808, and the expenditure £13,035. Amongst the specified returns of cases of diseases under injuries, 7938 are set down to metal "chips." Amongst diseases there were 330 cases of blepharitis, 331 of chalazion, 559 of keratitis, 516 of kerato-iritis, and 219 of leucoma and nebula; 586 of senile cataract and errors of refraction, 1338 of hypermetropia, 1040 presbyopia, 677 myopia, and 3157 cases of astigmatism of varied forms. Of convergent strabismus there were 1324 cases. Twenty-six cases of ophthalmia neonatorum were admitted.

A CONFERENCE ON MEDICINE IN INDUSTRY.—The annual week-end conference of the Institute of Industrial Welfare Workers, to be held at The Hayes, Swanwick, Derbyshire, from Sept. 26th to 29th, has chosen for its subject the Doctor and the Psychologist in Industry. On Saturday afternoon the subjects for discussion will be: What (1) Psychology, (2) Medical Science can do for Industry," the former being introduced by Dr. C. S. Myers, F.R.S., director of the Institute of Industrial Psychology; the second by Dr. W. F. Dearden, hon. secretary of the Association of Certifying Factory Surgeons. In the evening accident prevention will be dealt with from the psychological aspect by Dr. M. Culpin, lecturer on psychotherapy at the London Hospital; from the physiological aspect by Dr. H. M. Vernon, investigator for the Industrial Research Board. Discussions of a more general character will occupy the Sunday. The hostess is a well-known welfare worker, and other leading representatives of the welfare movement will take the chair at the several gatherings. The conference secretary is Miss N. J. Kessler, West Lynn, Altrincham, Cheshire.

CITY AND HOSPITALS' CHARITY ATHLETIC CONTEST.—To-day, Saturday, Sept. 6th, the third annual charity athletic contest between the Banks (holders), Stock Exchange, insurance offices, and hospitals, for the *Financial Times* challenge shield will be held at the Crystal Palace. Apart from the challenge trophy, which is held for a year by the institution scoring the greatest number of points, there are no prizes or awards of any kind. The athletes, who will include members of the British Olympic Games team, national and other champions, compete purely for the honour of representing their respective institutions and for the cause of charity. The programme consists of level flat events at 100, 220, 440, 880 yards, mile, three miles, and 120 yards hurdles, two miles walk, high and long jumps, putting the weight, and mile relay. In order that the entire proceeds may be divided between the London hospitals the *Financial Times* is again paying all expenses of the meeting. Tickets, 1*s.* 6*d.* (including admission to the Palace and covered stands), may be obtained from the hon. secretary, Mr. R. A. Lyons, at St. Bartholomew's Hospital, or from the *Financial Times*, 72, Coleman-street, London, E.C. 2.

NORTH WALSHAM WAR MEMORIAL COTTAGE HOSPITAL.—On August 27th the cottage hospital raised by the town and district of North Walsham as a memorial to the 179 men from the locality who fell in the late war was opened by Her Highness Princess Marie Louise. The total sum subscribed to build, equip, and endow the memorial amounted to £8700, and the hospital was opened practically free from debt. Sir Hamilton Ballance, hon. consulting surgeon to the new institution, referred at the opening ceremony to the need of an X ray installation for minor work in every cottage hospital, and hoped it would not be long before North Walsham had the necessary apparatus.

BOLINGBROKE HOSPITAL, WANDSWORTH COMMON, S.W.—The sum of £10,000 has been given to this hospital by Sir James and Lady Carmichael, of Kingston Hill Place, Kingston, towards the cost of erecting the William Shepherd memorial wing. The cost of this wing, when fully equipped, will amount to £60,000.

Appointments.

DICKSON, W. M., M.B. Ch.B., F.R.C.S. Eng., has been appointed Surgeon to Out-patients, Willesden General Hospital.

HART, E. R., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Hertford District of the County of Hertford.

NEILSON, J. P., M.B., Ch.B. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Llansawel District of the County of Carmarthen.

TUOHY, P. G., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Uckfield District of the County of Sussex.

Westminster Hospital Medical School: **WILSON, J. G.**, M.B., B.S., M.R.C.S., L.R.C.P., D.P.H. R.C.P.S. Eng., House Physician and Resident Medical Officer; **COLES, B. A.**, B.Sc. Wales, M.R.C.S., L.R.C.P., Resident Obstetric Assistant; **WILLIAMS, D.**, M.R.C.S., L.R.C.P., **HARRIS, I.**, M.R.C.S., L.R.C.P., House Physicians; **POOLE, E. B.** M.R.C.S., L.R.C.P., **ZIMMERMAN, M.**, M.R.C.S., L.R.C.P., **BENNION, F. R.**, M.R.C.S., L.R.C.P., House Surgeons; **DAVIES, M.**, M.R.C.S., L.R.C.P., Assistant House Physician; **DAVIES, J.**, M.R.C.S., L.R.C.P., Assistant House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, District Infirmary and Children's Hospital.—Hon. M.O. for Electro-Therapeutic Dept.

Barnsley County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Birmingham General Dispensary.—M.O. £550.

Bootle Borough Hospital.—Sen. M.O., also two Jun. M.O.'s. £150 and £125 respectively.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £120.

Bristol, Cossham Memorial Hospital, Kingswood.—H.S. £150.

Carshalton, Queen Mary's Hospital for Children.—Asst. M.O. £500.

Chester Royal Infirmary.—Asst. H.S. £150.

Coventry and Warwickshire Hospital.—Vacancy on Hon. Surg. Staff.

Dover, Royal Victoria Hospital.—H.S. £180.

Exeter, Royal Devon and Exeter Hospital.—H.P. £150.

Gloucestershire Royal Infirmary, Gloucester.—Asst. P. and Pathologist.

Halifax Royal Infirmary.—Third H.S. £150.

Leeds Public Dispensary.—Jun. Res. M.O. £150.

Maidstone, West Kent General Hospital.—Two H.S.'s. Each £220.

Manchester Education Committee.—Asst. Sch. M.O. £600.

Manchester University.—Asst. Lecturer in Chemical Pathology. £300–£500.

Middlesex Hospital and Medical School, W.—Surg. Reg. £300.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—M.O. for Out-patients. £125.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—H.P.'s and H.S.'s. Each £50.

Northampton County Mental Hospital, Berrywood.—Jun. Asst. M.O. £350.

Northampton General Hospital.—Hon. P.

Norwich, Norfolk and Norwich Hospital.—Cas. O. and H.S. £150.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s, H.P. Each £150. Also Jun. H.S. and H.P. Each £110.

Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg.

Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—Two H.S.'s. Each £150.

Sheffield Royal Infirmary.—Res. Surg. O. £200.

Sunderland Royal Infirmary.—Two H.S.'s. Each £140.

West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each £100.

Worksop Union Workhouse, &c.—M.O. £230.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments at Cwmbran, Monmouth, and Eyam, Derby.

The Secretary of State for the Home Department gives notice that, in consequence of the resignation of Dr. Clement Dukes, one of the Medical Referees under the Workmen's Compensation Act, 1906, a fresh appointment has to be made for the Districts of the Rugby and Daventry County Courts (Circuit No. 23). Applications should be addressed to the Private Secretary, Home Office, and should reach him not later than Sept. 20th, 1924.

Births, Marriages, and Deaths.

BIRTHS.

ALLEN.—On August 27th, at a nursing home, Highgate, the wife of Francis Allen, M.B., of a son.

HITCHINGS.—On August 26th, at Westfield, Hawkhurst, Kent, the wife of Dr. D. B. Hitchings, of a son.

MURPHY.—On August 26th, at "Stonefield," Kidbrook-grove, Blackheath, the wife of Denis V. Murphy, M.B., of a daughter.

ROPE.—On August 20th, the wife of Dr. A. D. Rope, of Quarry-place, Shrewsbury, of a son.

THOMAS.—On August 28th, at Clapham, London, to Dorothy (Dorothy S. Chamberlain, M.B., B.S. Lond.), wife of Cyril J. Thomas, M.R.C.S., L.R.C.P., of the County Mental Hospital, Lancaster—a son.

MARRIAGES.

BURTON—FREIR.—On August 28th, at Pinchbeck Parish Church, by special licence, Wilfred Robert Burton, L.R.C.P.I. and L.M., L.R.C.S.I., to Ethel, daughter of Mr. and Mrs. S. Freir, of Yew Tree House, Sharpe's Bridge, Spalding.

CAMPBELL—CHRIMES.—On August 28th, at Nevin, Carnarvonshire, John Maurice Hardman Campbell, O.B.E., M.D., of Oxford, to Ethel Mary, second daughter of Captain Chrimes, C.B.E., and Mrs. Chrimes, of Gresford.

DEATHS.

BAYLISS.—On August 27th, at St. Cuthberts, Hampstead Heath, Sir William Maddock Bayliss, M.A., D.Sc., F.R.S., Professor of General Physiology at University College, London, aged 64.

DEMPSTER.—On August 28th, William Thomas Dempster, M.B.E., M.R.C.S. Eng., L.R.C.P. Lond., of Brighton-road, Croydon.

GAMBLE.—On August 23rd, at Glen Maize, Donnybrook, Natal, Leonard Dobbin Gamble, M.B., C.M. Edin., late of Abergavenny, Mon.

LIPSCOMB.—On August 25th, at Trégastel, Brittany, the result of a boating accident, Eustace Henry Lipscomb, M.B., B.C. Cantab., J.P., of Holywell Hill, St. Albans, Herts, aged 64.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical News.

Society of Apothecaries of London.—As the result of recent examinations the following candidates passed in the undermentioned subjects:—

Surgery.—M. Bannounah, Guy's Hosp.; E. H. Boodrie, St. Mary's Hosp.; J. Crawford, Royal Free Hosp.; F. M. Deighton, Univ. Coll. Hosp.; C. S. Forrest, Manchester and Middlesex Hosp.; J. W. Graham, Manchester; J. C. C. Langford, Manchester and St. Bart.'s Hosp.; Z. Roodyn, Middlesex Hosp.; and C. W. Warne, Guy's Hosp.

Medicine.—F. M. Deighton, Univ. Coll. Hosp.; J. W. Graham, Manchester; G. L. W. Iredale, Edinburgh and St. Mary's Hosp.; W. R. S. Jaecques, Ghent; A. J. Moody and H. Morris (Sect. II.), St. Bart.'s Hosp.; W. E. Pennington, Liverpool; Z. Roodyn, Middlesex Hosp.; and J. G. E. Vachell, St. George's Hosp.

Forensic Medicine.—H. L. Bernstein, Guy's Hosp.; A. K. A. Carter and F. M. Deighton, Univ. Coll. Hosp.; R. C. Glover, Leeds; J. W. Graham, Manchester; A. J. Moody, St. Bart.'s Hosp.; W. E. Pennington, Liverpool; B. A. Perott, Petrograd; M. Schwartzman, Odessa; and Z. Roodyn, Middlesex Hosp.

Midwifery.—W. Bentley, Birmingham; F. M. Deighton, Univ. Coll. Hosp.; J. W. Graham, Manchester; J. C. C. Langford, Manchester and St. Bart.'s Hosp.; E. J. P. McDowell, St. Thomas's Hosp.; W. E. Pennington, Liverpool: and Z. Roodyn, Middlesex Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: J. Crawford, F. M. Deighton, J. W. Graham, G. L. W. Iredale, J. C. C. Langford, H. Morris, Z. Roodyn, and J. G. E. Vachell.

Diploma of Laryngology and Otology of the Conjoint Colleges.—In the article upon Special Diplomas in the Students' Number of The Lancet, published last week, there was an omission to mention the special Diploma in Laryngology and Otology granted by the English Conjoint Board (D.L.O.). This Diploma was instituted in 1923, and the conditions for obtaining it follow the accepted pattern. Candidates must possess a registrable qualification, and will be examined in the anatomy, physiology, medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea, bronchi, and œsophagus. The examination takes place twice yearly, and notice of entry, with fee of £6 6*s*., should be sent 14 days previously to the Secretary, Examination Hall, Queen-square, London, W.C. 1.

Fellowship of Medicine and Post-Graduate Medical Association.—On Sept. 8th a three weeks' course in ophthalmology commences at the Royal Westminster Ophthalmic Hospital. Clinical instruction will be given every afternoon from 2 o'clock and special demonstrations three times a week on methods of examination, fundus class, and common affections of the eye. A fortnight's course has been arranged at the Infants Hospital from Sept. 15th to 27th. The syllabus deals with diseases of infants from various aspects and consists of clinical demonstrations, "round table" consultations, lectures, &c. Three visits of inspection are to be made: To St. Margaret's Hospital for Ophthalmia Neonatorum, Thavies Inn (Holborn), and the Nursery Training School (Golders Green). A fortnight's intensive course in medicine, surgery, and the various special departments will be held at the Westminster Hospital from Sept. 22nd to Oct. 4th, of which further particulars will be shortly published. Dr. Porter Phillips and Dr. Thomas Beaton will give a series of lecture-demonstrations on Tuesdays and Saturdays, at 11 A.M., in psychological medicine at the Bethlem Royal Hospital from Sept. 30th to Oct. 25th. Courses arranged for October are: Diseases of children, diseases of the ear, nose, and throat, electrotherapy, tropical medicine, urology, and a fortnight's intensive in medicine and surgery and other departments. Full particulars can be obtained from the Secretary of the Association, 1, Wimpole-street, W. 1.

University College Hospital, London.—The annual dinner of the past and present students of University College Hospital will be held at the Hotel Cecil on Friday, Oct. 3rd, at 7.30 P.M. Dr. Michael Foster, O.B.E., will be in the chair. Tickets can be obtained from the secretaries, Mr. Gwynne Williams and Prof. T. R. Elliott, University College Hospital Medical School.

Donations and Bequests.—By will the late Mr. Richard Stanley Varley, after certain minor bequests, left the residue of his property, about £20,000, to his brother Gilbert with the request, but without creating any trust in the matter, that if circumstances hereafter should permit, there should be paid £2000 to Magdalen College, Oxford, for the Alec Varley Fund, and the balance of the residue to the Vice-Chancellor of the University of Oxford, for the advancement of science, and in particular for medical research.

Cumberland Infirmary, Carlisle.—A gift of £1500 has been received by this infirmary from Mr. P. H. Holt, High Sheriff of Cumberland, for the purpose of establishing a pathological laboratory at the institution. At a recent quarterly meeting of the governors Dr. N. Maclaren said that the need for such a laboratory had been felt by the staff for a long time, and its provision would mark a new era in the life and utility of the Cumberland Infirmary.

King Edward's Hospital Fund for London: King's College Hospital.—In accordance with the decision of the Fund to apply the legacies of the late Mr. and Mrs. John Wells, estimated at over £200,000, to extensions, improvements, and other special needs of hospitals, a grant has been made to enable 14 additional beds for accident cases to be opened at King's College Hospital. The need for additional accommodation for accident cases was emphasised in the report, issued last spring, of a special committee of the Fund.

Brighton and Rose Day.—The allocation has just been made of the proceeds of Alexandra Day in Brighton and district, which amounted to £750. The distribution was as follows:—Royal Sussex County Hospital, £275; Royal Alexandra Hospital for Sick Children and the Sussex Maternity and Women's Hospital, each £73; Brighton and Hove Dispensary, £80; Lady Chichester Hospital and the new Sussex Hospital, each £48; Eye Hospital and Queen's Nurses, each £31 10*s*.; Surgical Aid Society, £22; and the Brighton Dental Hospital and the Clayton and Keymer Nursing Association, each £10.

Manchester Royal Eye Hospital.—The annual report for 1923 states that 30,502 out-patients and 2046 in-patients were treated; the average length of stay in the hospital of the in-patients was 19·1 days. The number of accidents treated was 8497, an average of 23·3 per day. The income from all sources was £18,808, and the expenditure £13,035. Amongst the specified returns of cases of disease under injuries, 7938 are set down to metal "chips." Amongst diseases there were 330 cases of blepharitis, 331 of chalazion, 559 of keratitis, 516 of kerato-iritis, and 219 of leucoma and nebula; 586 of senile cataract and errors of refraction, 1338 of hypermetropia, 1040 presbyopia, 677 myopia, and 3157 cases of astigmatism of varied forms. Of convergent strabismus there were 1324 cases. Twenty-six cases of ophthalmia neonatorum were admitted.

A Conference on Medicine in Industry.—The annual week-end conference of the Institute of Industrial Welfare Workers, to be held at The Hayes, Swanwick, Derbyshire, from Sept. 26th to 29th, has chosen for its subject the Doctor and the Psychologist in Industry. On Saturday afternoon the subjects for discussion will be: What (1) Psychology, (2) Medical Science can do for Industry," the former being introduced by Dr. C. S. Myers, F.R.S., director of the Institute of Industrial Psychology; the second by Dr. W. F. Dearden, hon. secretary of the Association of Certifying Factory Surgeons. In the evening accident prevention will be dealt with from the psychological aspect by Dr. M. Culpin, lecturer on psychotherapy at the London Hospital; from the physiological aspect by Dr. H. M. Vernon, investigator for the Industrial Research Board. Discussions of a more general character will occupy the Sunday. The hostess is a well-known welfare worker, and other leading representatives of the welfare movement will take the chair at the several gatherings. The conference secretary is Miss N. J. Kessler, West Lynn, Altrincham, Cheshire.

City and Hospitals' Charity Athletic Contest.—To-day, Saturday, Sept. 6th, the third annual charity athletic contest between the Banks (holders), Stock Exchange, insurance offices, and hospitals, for the *Financial Times* challenge shield will be held at the Crystal Palace. Apart from the challenge trophy, which is held for a year by the institution scoring the greatest number of points, there are no prizes or awards of any kind. The athletes, who will include members of the British Olympic Games team, national and other champions, compete purely for the honour of representing their respective institutions and for the cause of charity. The programme consists of level flat events at 100, 220, 440, 880 yards, mile, three miles, and 120 yards hurdles, two miles walk, high and long jumps, putting the weight, and mile relay. In order that the entire proceeds may be divided between the London hospitals the *Financial Times* is again paying all expenses of the meeting. Tickets, 1*s*. 6*d*. (including admission to the Palace and covered stands), may be obtained from the hon. secretary, Mr. R. A. Lyons, at St. Bartholomew's Hospital, or from the *Financial Times*, 72, Coleman-street, London, E.C. 2.

Notes, Comments, and Abstracts.

RED CROSS WORK.

IN the able hands of its late Chief Executive Officer the Red Cross was becoming more and more associated with the reorganisation of hospitals throughout the country. On the death of Sir Napier Burnet, the Joint Council appointed Dr. F. N. K. Menzies as Director of the Department of Hospital Medical Services, and a report from him, including special articles of general interest to hospital workers, will be issued in the autumn. The present report[1] deals with the other work of the Joint Council. Although we are now six years from the armistice the Joint Council is still assisting many officers and ex-officers suffering from pulmonary and other forms of tuberculosis. These cases unfortunately show no signs of decreasing, and relapse is all too frequent. The Auxiliary Hospitals for Officers Department refunds hospital stoppages to necessitous pensioned and half-pay officers in sanatoriums, hospitals, and nursing homes, and so relieves them of anxiety for the welfare of their dependents. Since comparatively few patients are fit to start work immediately on discharge, it is customary to make a small weekly grant for extra diet and an additional grant for maintenance. The Department also helps ex-officers with the expenses of sanatorium treatment while their cases are under consideration by the Ministry of Pensions or the Officers' Appeal Tribunal, and, in cases pronounced ineligible but deserving and necessitous, the patient is given the chance of a reasonable period of sanatorium treatment. During the winter 1923–24 the Department made travelling arrangements for and gave *financial assistance to a number of lung cases sent out to* Switzerland and the Riviera by the Ministry of Pensions, the destination being Sunny Bank, San Remo (19 cases), Sanatorium Davos-Dorf (14), Palace Hotel, Montana (12), Sanatorium Altein, Arosa (10), Clinique Quisisana, Leysin (4), Chateau Mer et Mont, Mentone (4), and other places in smaller number. Emergency help was given on a large scale in the form of maintenance grants to the families of tuberculous ex-Service men while awaiting admission to the sanatorium, during their stay, and for a reasonable time after. Borough Emergency Help Committees are now represented on local tuberculosis care committees and overlapping is thus avoided.

The Home Service Ambulance Committee aims at bringing suitable means of transport within reasonable reach of the sick and injured in all parts of the country, and there are now 333 home service ambulance cars working in England, Wales, and Ireland. Without such cars, as the report pointedly states, much of the benefit of recent scientific discovery would be inapplicable to patients who are at any distance from a hospital. The Committee aims not merely at distributing ambulances but establishing an ambulance service attended by men and women with proper qualifications, and it is becoming the normal practice for members of the Order of St. John or British Red Cross Society to accompany the ambulance at every call. Home service ambulances are also available for various public duties; for the use of factories as required by the Home Office, to provide means for removal of serious cases of sickness and injury; and for the coal-mines, where men working in the pits drive and attend the ambulances during their rest periods. Home service ambulances are attending more and more at football matches, race meetings, and other crowded gatherings where casualties may occur amongst spectators. During a recent omnibus and tram strike they undertook the conveyance of out-patients to various hospitals in London. The recent conference on ambulances recommended local authorities to pay a mileage fee for ambulances sent for by the metropolitan police, and the War Office has recently recommended the various commands to use the service for the transport of military cases to hospital when other vehicles are not available. One ambulance has been fitted up as an X ray car, after being used as such on the Italian front and since maintained by the College of Ambulance. With the coöperation of the Institute of Radiology, radiographic diagnosis has thus been rendered available at the patient's home, the apparatus being erected in the bedroom and connected by means of cable to the dynamo attached to the car. Since the ambulance service has been instituted something like a quarter of a million cases have been carried in these ambulances, nearly 50,000 by 11 ambulances in West Lancashire alone, and in other counties the numbers run into thousands. This kind of Red Cross work deserves fuller recognition from the public than it now receives.

A NEW VACCINATION ORDER.

THE Minister of Health has issued a new Vaccination Order for England and Wales, which will come into force on Oct. 1st. Hitherto under the Vaccination Order of 1923 the parent or person registering the birth of a child has been given "Form A," which requires that the child shall be vaccinated, and if the parent has any conscientious objection to the operation, he must apply for an additional form on which to make the statutory declaration. From Oct. 1st, under the new Order (Vaccination Order, 1924), Form A includes a form of declaration of conscientious objection. The effect of the new Order will be to facilitate procedure for the objector.

THE COLLEGE OF AMBULANCE, LTD.: THE CASE OF COLONEL PARKINSON.

THE recent case in connexion with the sale of honours appears to have reflected unfairly upon the College of Ambulance, Ltd., so that our readers ought to be reminded of the facts. Lieut.-Colonel G. W. Parkinson claimed from the College of Ambulance, Ltd., and their secretary, Mr. E. E. Harrison, £3000 on the ground that the money had been paid as a contribution to the funds of the College on the faith of representations by Harrison that in return he could, and would, procure for the plaintiff the honour of knighthood. Under the judge's direction the jury answered questions left to them by the judge as follows:—

1. (*a*) Did Harrison represent that he was in a position to undertake that the plaintiff would receive a knighthood?—Yes. (*b*) Or did he only promise to use his influence for that purpose?—No.
2. (*a*) Was that statement false?—Yes. (*b*) Fraudulent?—Yes.
3. Was the plaintiff induced thereby to part with his £3000?—Yes.
4. Did the plaintiff contract with Harrison personally, looking only to him for securing the knighthood?—No.
5. Did he contract with him in the belief that he was acting for and had the authority of the College in giving the undertaking?—Yes.
6. Was Harrison in fact so authorised, or was he held out by the College as so authorised?—Certainly he was held out as so authorised, and we consider he was so authorised.
7. Did the plaintiff knowingly mislead the council into thinking that he was making a voluntary donation?—No.
8. Damages?—£3000.

A verdict of the jury on the facts having thus been taken, argument took place as to whether any action could be maintained or money recovered upon such a contract as had been revealed. Mr. Justice Lush held that the action must be dismissed, but deprived Harrison of his costs, saying that he had increased the costs of the litigation by denying fraud, and causing the plaintiff to be cross-examined at length, and yet had not gone into the witness-box or called witnesses to meet the charge of fraud. A contract, his Lordship held, to guarantee or undertake that an honour would be conferred by the Sovereign if a contribution were made to a public charity, or some other service rendered, was against public policy, and therefore an unlawful contract to make, and one that could not be sanctioned or recognised by a court of justice. On the question whether the plaintiff could recover the money paid either from Harrison or from the College of Ambulance, he did not lay down that in every case of a contract against public policy, where one of the parties had defrauded the other, the plaintiff would be unable to recover; but that where there was an element of turpitude and the parties were in *pari delictu*, neither could recover against the other. The plaintiff knew that he was entering into an improper contract and he ought not to have made it. The plaintiff was not entitled to recover from the College on the ground that it had benefited through its agent, the illegality of the contract precluding him.

Mr. Justice Lush said that the questions as to whether the College had authorised or held out Harrison as authorised to promise a knighthood in return for £10,000 to the College, had been put by him, subject to doubt in his own mind as to whether there was evidence on which the jury could find that there was such authority. He now held that there was no evidence to justify the findings arrived at, but went on to say that if there had been, it would have made no difference to the result of the action, the contract being in itself illegal. Mr. Justice Lush's pronouncement with regard to the connexion of the College of Ambulance with the undesirable acts of its secretary, must have been eminently satisfactory to those responsible for its management, upon whom the jury's verdict cast what, in the judge's opinion, was an unmerited slur. Any charitable institution may rightly feel satisfaction at seeing rewards in the form of titles bestowed upon its supporters in recognition of their munificence. Those responsible for the finances of hospitals and similar institutions should, however, be agreed that charity must be its own reward in the great majority of cases, and they must be of one mind with the judge in holding that any bargain to secure a recompense such as knighthood for a prospective donor is contrary to public policy. A bare offer to endeavour to procure such recognition is equally undesirable. Any power to procure honours and rewards supposed to be possessed by members of a particular board of management would at once confer upon it an unfair and undeserved advantage over other like bodies, and no doubt some, besides those persons directly interested in the recent litigation, will have noted the unenviable publicity which litigation has involved.

---

[1] Fourth Report of the Joint Council of the Order of St. John of Jerusalem in England and the British Red Cross Society, covering the period from April 1st, 1923, to March 31st, 1924.

CONCERNING LEFT-HANDEDNESS AND STAMMERING.

To the Editor of The Lancet.

Sir,—The sinister associations of left-handedness[1] were recognised by the Early Church. The Nestorian Christians of India attribute to the ministrations of St. Thomas, the apostle, their conversion to the faith, and there can be no doubt that Christianity was established on the coastal regions of India at a very early period. The traditions of the Early Church give very curious information as to the strange manner in which the Saint travelled to these parts of the world, and of his work and sufferings in the East, where (as the "Golden Legend" has it) he preached the Gospel to the miscreants. In the apocryphal "Acta Sancti Thomæ," which record his evangelisation among the peoples of India, there is an incident recorded where the Saint persuaded a newly-wedded pair to a life of Christian asceticism; with an account of the arguments he made use of, some of which are distinctly "modern" (shall we say?) in their tone. He told them that if they adopted this course of life they would avoid much trouble both for themselves and for any potential offspring, drawing for their benefit a brief but sufficiently vivid account of the possible undesirable eventualities attendant upon the multiplication of what perhaps he secretly considered to be an undesirable stock.

The descriptions as given in the various languages in hich this story has come down to us are in substantial greement,[2] but the Amharic version introduces an interesting variant in giving left-handedness as one of the stigmata eld out to the young couple as a possible result of their perpetuation of their race. It has been translated by Sir E. A. W. Budge from the collation of two MSS. in the British Museum,[3] and the argument made use of by St. Thomas runs as follows. If his auditors follow his advice, "then will ye escape labour and sufferings, both the seen and the unseen; and ye shall be free from worldly cares, and the children who would form your posterity will not come into being. If ye beget many children ye will, for their sakes, become avaricious oppressors, and ye will afflict the orphan and the widow, and ye will become unjust persecutors. And if ye do all these things, ye will suffer sore chastisement. And the greater number of children become wicked and fall into error, for devils attack them either secretly or openly, or they become mad, or foolish, or deaf, or left-handed, or lame, or paralysed. If they escape these things they become unprofitable evildoers, or workers of abominations, or they become the companions of avaricious men and thieves, and in any case ye suffer labour and sorrow."

This catalogue of *vitia* allied in their incidence to left-handedness is significant: insanity, deafness, paralysis, deformity, criminality, and other forms of anti-social defect. The Greek text[2] gives in addition blindness, dumbness, "half withered"-ness, adultery, murder, and theft. A personal experience of my own may be of interest in this connexion of left-handedness. Twenty years ago or more, during my student days, I was taken with the idea that it would be very excellent if, in surgery, I could use either hand indifferently. With this end in view I practised using the left hand and, amongst other things, taught it to write. It was not long before I could write (as I still can) legibly, though not very quickly, with the left hand; but an immediate effect was that my normal (right-handed) writing suffered marked alteration for the worse, and this deterioration has been permanent.

In the Manchester *Evening Chronicle* for August 20th there is an account of how on that date at the Royton Police Court a domestic servant was bound over after pleading guilty to theft, having broken into her employer's house while he was away on holiday, stolen some money, and gone away leaving the house open. Her employer, who put in a plea of leniency on her behalf, is reported as saying, "Her history was a very sad one. She stammered badly as the result of shock through finding her father hanging when she was a little girl." There is no mention of her being left-handed or anything of that sort, but this correlation of stammering and conveying (as wise men call it) has a certain significance at the present moment.

For those who are interested in the subject of left-handedness there is quaint reading to be found in the fifth chapter (Of the Right and Left Hand) of the fourth book of Sir Thomas Browne's "Pseudodoxia epidemica" (1646).

I am, Sir, yours faithfully,
Sinistré.

August 27th, 1924.

UNSIGHTLY WARTS.

To the Editor of The Lancet.

Sir,—In reply to Dr. G. S. Sander (The Lancet, August 2nd, p. 256), a young woman had a wart so large it resembled a black teat under her chin. By my suggestion she washed it with carbolic soap, also damped it slightly and rubbed the soap against it so as to leave a little about it. It soon disappeared, leaving no trace. I have never seen warts which carbolic soap used in that way would not quickly cure.

I am, Sir, yours faithfully,
M. L. J.

August 26th, 1924.

To the Editor of The Lancet.

Sir,—May I suggest to your correspondent that he try the effect of surgical diathermy on the multiple soft warts which are annoying his patient. One method of application is described by Saberton on p. 105 of his small text-book ("Diathermy in Medical-Surgical Practice." Cassell and Co. 1920). I have modified this method in my own practice, connecting the patient directly to the Tesla pole and earthing, as does Saberton, through a pointed probe which I hold in my own hand. This makes the condenser couch superfluous. The spark gaps on the diathermy machine are at first closed down as far as possible until the wart is partially anæsthetised and a thin layer of desiccated tissue covers the surface. It is then necessary to open the spark gaps and increase the current somewhat in order to desiccate the growth completely. The method is practically painless, usually efficacious in a single sitting, and so far I have not seen any scars.—I am, Sir, yours faithfully,

Rosslyn Earp.

Antioch College, Ohio, U.S.A., August 20th, 1924.

GRATUITOUS MEDICAL ATTENDANCE.

To the Editor of The Lancet.

Sir,—Your issue of August 16th contains a letter signed "Inquirer" and a commentary by yourself which embrace what I have always believed to be the sentiments of the entire profession; at any rate, my own experience has been that no doctor or dentist has ever accepted a fee from me, though I have never failed to press an offer of pecuniary reward for services rendered. That I have been fortunate is evident from the fact that many of my colleagues in the Services, particularly the Navy, have been charged, in some cases quite large sums, for professional services rendered to themselves or their wives, the larger sums being frequently marked "half fees."

Are we to understand that there are amongst our professional brethren those who repudiate that relationship because our practice is confined to our own Services?

I enclose my card, and am, Sir, yours faithfully,
Mars.

August 27th, 1924.

THE HAZEL LUXURY SHOE.

A shoe with a wool-felt lining has the advantage of being comfortable and of keeping the foot dry and warm, but the general use of such shoes has been impeded by the cost of production involved in sewing a felt sole to the boot by hand. Messrs. Crick and Co., boot manufacturers of Northampton, with branches in London and the suburbs, have overcome the difficulty by a patent process of manufacture. In these shoes, which we have tested, the insole of wool-felt is a quarter of an inch thick, and although compressed in walking retains its resiliency. No doubt so absorbent a material is more likely to retain perspiration, an objection which can be met by more frequent change of socks. To those who suffer from cold feet or who need to be careful to keep their feet warm, a shoe of this kind should prove of value.

FOOD VALUE ON LIFEBOATS.

Though the Board of Trade appears to have on its staff no official medical adviser, it has yet made a definite advance in ordering that, to the biscuits and water carried in the boats of merchant ships for use in emergency, there shall be added from July, 1925, one pound of condensed milk for each person the boat is certified to carry. This will raise the proportion of fats and the total caloric value of the food available. The difficulty of distribution may be serious, and that inclines us to regret that a solid ration of chocolate had not been ordered instead. Water is in boats carried in small flat casks, breakers, and is distributed with a tiny enamelled-metal bucket, the diameter of a man's thumb and the length of two. The little bucket is dropped into the breaker through the bung-hole and so filled that none of the precious fluid may be lost in the pouring of it out. Chocolate in bars would keep very well in the biscuit tank, and, marked in ounce or half-ounce lengths, could be easily served out. We hope the officers of the Board of Trade will give further thought to food values when providing for the needs of the shipwrecked.

PUBLIC HEALTH IN PALESTINE.

A REPORT on the administration of Palestine just presented to Parliament by the Colonial Office contains the following statements with regard to health in the mandated territory. The organisation in the last three years, and the higher standard of professional knowledge inculcated in all sections of its staff by means of regular courses of training, have enabled the Health Department to hold in check the diseases—malaria, enteric fevers, typhus, and small-pox—which in the past ravaged the country. Measles broke out more than once in epidemic form with pneumonic complications, causing heavy mortality among children. Small epidemic units with nurses served some affected areas with good results; about 5000 cases, with a death-rate of 18 per cent., were reported. Measles is, therefore, chiefly responsible for a large increase in the death-rate, which for the first 11 months of 1923 was 25·03 per 1000, as compared with 18·75 per 1000 in 1922. There were restricted outbreaks of plague in the summer at Jaffa (11 cases, one death) and Haifa (four cases, one death). The efficiency of the antimalarial campaign has been maintained; economies in its cost have followed the measures taken to protect cisterns and clear swamps under the Anti-Malarial Ordinance, and with the ready coöperation of the inhabitants, now appreciative of the benefits derived from antimalarial operations. The most notable results have been achieved in the once malaria-ridden Valley of Esdraelon. The menace of the anopheline mosquito has been banished from the large towns, and the established control of culex breeding renders almost unnecessary mosquito nets or the mosquito-proofing of houses. In the attainment of these results the two American units, the Malaria Research Unit and Malaria Survey Section, have given invaluable service. Palestine is also indebted to the workers in, and subscribers to, the voluntary and missionary hospitals, without whose unremitting care and constant help the progress made during the past two years would have been impossible. Improved water supplies in towns and villages, where springs have been guarded from pollution and piped, and stricter supervision of public establishments helped to lessen the incidence of enteric fevers. The occurrence of typhoid and typhus was almost altogether confined to immigrants from Central Europe.

On the closure of the travelling ophthalmic hospital and ancillary clinics special ophthalmic clinics at Government hospitals and dispensaries were formed, and are conducted by medical officers who have taken a course of instruction at an ophthalmic "training centre" in Jerusalem, under the chief surgeon of the British Order of St. John of Jerusalem Ophthalmic Hospital, Jerusalem. The travelling hospital had since August, 1919, treated 14,148 patients; the total attendances were 81,848 and 5378 operations were performed. 18·3 per cent. of its patients were blind in one or both eyes. The medical inspection and treatment of children in Government schools, particularly for eye disease and parasitic and verminous condition of hair and skin, have been attended with success.

At Kantara quarantine control was abolished, and will be exercised in future during the pilgrimage season only, or if extensive epidemics develop in Egypt. As from September, travellers arriving at Samakh and Ras el Nakura by motor-car route from Baghdad were placed under medical surveillance against cholera and small-pox. Ship and passenger inspection at the ports was conducted without interruption. At the end of 1923 there were seven Government general hospitals dieting for 168 patients, and a mental hospital at Bethlehem dieting for 40 patients. The sanitation of villages progressed only where local councils exist. Notification of births and deaths is more regular, and infectious disease, except of the minor type such as measles, is reported more readily under the stimulus of periodical visits by medical officers. Laudable efforts have been made in some towns to improve the primitive drainage systems.

A serious increase of rabies in dogs and jackals, reflected in a greater number of human victims, has demanded an organised campaign. Antirabic vaccine is now prepared and distributed directly by the Health Department. There were 11 cases of hydrophobia, all fatal. Circulars to enlighten the public were published. The number of lepers in Palestine does not now exceed 80; of these 30 are in the Moravian Society's Leper Home, Jerusalem.

The central laboratories of the Health Department, with bacteriological, chemical, and antirabic divisions, are in Jerusalem, and there are clinical laboratories at Jaffa and Nablus; these, with the laboratory of the Malaria Research Unit at Haifa, and the laboratories of the Hadassah Medical Organisation at Jerusalem, Jaffa, Haifa, Tiberias, and Safed, ensure, by close coöperation, rapidity of diagnosis and analysis of specimens throughout the country.

The voluntary hospitals and dispensaries, despite diminished funds, treated 20,000 in-patients in 1923. In regard to the training of nurses, a higher and more uniform standard was reached in examinations than in previous years, in both Government and voluntary hospitals. In the Rothschild Hospital, Jerusalem, more than 40 nurses are undergoing instruction. In the Midwives' Training School of the Government Hospital, Jerusalem, 11 women (as against three in 1922) passed the qualifying examination. Licences to practise were granted to 80 doctors, 39 dentists, 22 pharmacists, and 28 midwives. The medical and dental professions are becoming seriously overcrowded. The wholesale trade in drugs and poisons is more strictly controlled. Special certificates are issued for the import of the dangerous narcotic drugs controlled by the Imperial Opium Convention; the amounts imported in 1923 were: cocaine, 9965; morphine, 710; codeine, 2384; and heroin, 1398 grammes.

A HOME BUBBLY-BATH.

EFFERVESCING baths have been employed for their sedative and tonic action in neurasthenia and certain conditions of cardiac disturbances; at Nauheim they have long been the recognised treatment for cardiac dilatation, and the whirlpool bath introduced at many Red Cross institutions during the war was found of value not only in cases of muscular and articular trouble, but also in systemic affections. The Aerophor Pearl Bath Apparatus (J. Wenger, 65, Hayter-road, London, S.W. 2) is designed to provide at home an effervescing bath so as to avoid the trouble and expense of visiting a spa. Effervescence is produced in one type by an electro-motor to be connected with the electric-light supply, and in other types by a small turbine, compressed air being liberated through minute holes in a grid at the bottom of the bath over which is placed a wooden rack. The aeration is claimed to allow a higher temperature of water to be used, and to result in a tonic quality which the ordinary bath does not possess. The bath is, we understand, in extensive use at hydropathic establishments and holiday resorts in Switzerland, as well as at a number of Swiss hospitals, and medical testimonials from America show its appreciation there in cardiovascular and certain types of neurotic disorder.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 8th, to SATURDAY, Sept. 13th.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars. Clinical Instruction in the Out-patient Department every afternoon from 2.30 P.M. Venereal Clinic Tuesday and Friday from 5.30 to 7 P.M.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross. Clinical instruction every afternoon from 2 P.M. Wed., 5 P.M., Mr. Giblett: Clinical Demonstration on Common Affections of the Eye. Thurs., 5 P.M., Mr. Morgan: Fundus Class. Fri., 10 A.M., Mr. Hine: Methods of Examination.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Mon., 5 P.M., Mr. Bathe Rawling: Cerebral Surgery.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Sept. 8th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Pernet: Skin Dept. 2 P.M., Dr. Gibb: Eye Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—11 A.M., Mr. Dudley Buxton: Dental Dept. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M. In-patients, Out-patients, Operations, Special Departments.

An Address

ON

SOME VARIATIONS FROM THE NORMAL TYPES OF HUMAN METABOLISM.

Communicated to a Joint Meeting of the Liverpool Medical Institution and the Manchester Medical Society, Session 1923–24,

BY CHARLES J. MACALISTER, M.D. EDIN., F.R.C.P. LOND.,

LECTURER ON CLINICAL MEDICINE, UNIVERSITY OF LIVERPOOL;
HON. PHYSICIAN, LIVERPOOL ROYAL SOUTHERN HOSPITAL.

AT the meeting of the British Association last year Sir Oliver Lodge, in an inspiring address on Man and the Universe, spoke of the doctrine of the ascent of man as being a hopeful one, because it explained so much. It explained our imperfections. He referred to man as a newcomer in a world whose antiquity is now estimated at 400 million years. "He is unfinished—still in the process of becoming and not complete." Although Sir Oliver Lodge was referring more particularly to defects other than physical there is no doubt that they, whether anatomical or chemical or both, are to be included among those which he said "could be understood and explained as stages in the process of development towards an ideal which lay ahead."

As medical men we are constantly confronted with problems upon which these fundamental truths have a direct bearing. In the process of evolution man has attained to what may be regarded as an average physiological perfection, but we frequently meet with variants from such a standard—some, as far as we know, purely structural, others definitely metabolic or chemical—which indicate that ancestral, or it may be reversionary, characteristics are present. These account for departures from health concerning which our help is often sought, and their study is interesting, not only from an evolutionary standpoint, but also because their origin occasionally throws light upon the most successful measures which may be taken for their correction or alleviation.

Man's present stage of development has probably been acquired through ancestral conditions of environment and opportunity, and these have led to his having structural and physiological complexities which present considerable variations. His habits as to food must have undergone extraordinary alterations, and his capacity for metabolising almost any types of food have surely resulted from great developmental changes in modern as compared with primitive types. The lower animals, so far as I am aware, have fewer of these complexities. They are in the main carnivorous or vegetarian, as the case may be, in their dietetic habits—and man's ancestry included both of these classes. A falling back to prototype may accord to him a lessened capacity for mixed metabolism, and it is this assumption that I go on to discuss.

DIETETIC METABOLIC VARIATIONS THE RESULT OF REVERSIONS.

I would suggest that dietetic variations of metabolism in man result from reversions, sometimes towards a carnivorous, sometimes towards a vegetarian type of ancestry, and if this be so, we must take it that there was a common stock from which these types originated. In the carnivora there was a latent or undeveloped vegetarian metabolism, whereas in the vegetarian primate type there was a latent carnivorous one. This hypothesis explains the possibility of there being an adaptability to new dietetic conditions on the part of primitive man as he emerged from the vegetarian or primate stage. With the development of the carnivorous instincts the latent carnivorous metabolism to which I have referred would become more and more highly developed, and by degrees the organs and secretions necessary for a mixed feeder would become evolved; changes would take place in the encrinoid secretions, and there would be retrogression of other parts whose utility had become lessened in the new circumstances. It is on this account that vestigial remains play such an important part in the problems of metabolism which mainly interest me. In this relation I would recall how the embryo and fœtus in the course of development illustrate many of the types belonging to postnatal conditions of former orders before the birth of the perfected infant man: (1) Protozoal type —unicellular germ-plasm; (2) notochord with gill slits; (3) budding limbs; (4) perfected limbs and well-developed tail of placental mammal with muscles for wagging it which afterwards become ligamentous and fixed; (5) up to sixth month the lanugo reminiscent of a period when hairy covering was essential as a permanent structure in ancestry; (6) in the fœtus 15 mm. long the milk streak containing the anlage of several pairs of breasts, which all disappear in the process of development except the normal permanent pair.

It needs very little stretch of imagination to consider how, by persistence postnatally of one or other of the characters of former ancestries, may be explained some of those permanent anatomical and physiological imperfections which account for idiosyncrasies of metabolism.

ANATOMICAL VARIATIONS IN RELATION TO PERSONAL IDIOSYNCRASIES.

In 1908, in a paper on the "Personal Factor in Diet,"[1] I directed attention to an example of this influence of a developmental arrest in the case of an individual presenting well-marked symmetrical polymastia, who had very limited capacity for metabolising the fleshes. In the years which have intervened many of these cases have come under notice, and an interesting observation in relation to polymastia which I made, when pathologist to the hospital, was the occasional association of a long spiral appendix, sometimes presenting a funicular opening, thus resembling what is normal in the anthropoid apes. Polymastia is sometimes regarded as an evidence of degeneration, and its subjects as possessing mental qualities of a decadent character. My own experiences do not confirm this. I prefer to regard it as resulting from an arrest of development which leaves the individuals with a physiology of a specialised type. Their intelligences and characters have usually been normal. But the important point is that, although they are generally mixed feeders and present in most cases full powers of digesting and utilising vegetable foods, they are truly reversionary so far as their animal protein metabolism is concerned, insomuch that, like the carnivora, their flesh-containing meals require to be taken at much longer intervals than is the case with average normal persons.

I have mentioned this type of case to indicate that there are people who present anatomical variations coincident with and throwing light on their idiosyncrasies. Quite recently a man has presented himself who suffered from severe attacks of indigestion for more than 20 years. There were sometimes considerable intervals of freedom from pain, but when the attacks began they tended to continue for long periods. There were anorexia, splitting headaches, pain and flatulence after food, and marked constipation. On examination a multiple polymastia was found. There was a pair of phantom areolæ in the seventh interspaces and another abdominal pair. It turned out that his dyspepsia was of ingravescent type—that is, it got worse as the day went on; often absent after breakfast, marked after his midday meal, and very severe after the evening one, the discomfort lasting well into the night and disturbing his rest. A further interesting note was the history of pains in his joints which he had ascribed to rheumatism, and he informed me that his father and mother, especially the former, had suffered from arthritic conditions. This type of dyspepsia is not uncommon, apart altogether from any visible evidences of arrested development, and I have little doubt that it depends on deficiencies of secretion and of elimination which bring it into the broad categories of gout. In other words, such dyspepsias result from idiosyncrasies or imperfections of metabolism which are probably reversionary.

---

[1] Liverpool Medico-Chirurgical Journal, 1908.

The flesh-eating animal is a slow metaboliser. It lives generally on one meal a day, and in some instances such a meal is sufficient to sustain it for a longer period. The human being who has inherited a dominant carnivorous type of metabolism bears qualities which are reminiscent of what is normal in the pure carnivore. Convention and tradition have taught John Bull that three, often pretty substantial, meat-containing meals are likely to keep him fit. Perhaps most normal people can and do thrive on such a régime, but in those variants whose metabolism and powers of elimination cannot keep pace with the intake of fuel a breakdown occurs sooner or later, and the gouts appear. The inadequate organs are continually in a condition of overstrain owing to absence of metabolic rest-periods; health becomes impaired, and often enough life is shortened.

Perhaps I can best explain these rest-periods by means of diagrams which illustrate how waste products become stored up when idiosyncrasy is not met (Figs. 1 and 2). The remedy for these cases is not far to seek; it simply involves an imitation during the day of what occurs during the night. There are many degrees of this type of inadequacy which could be investigated scientifically by chemical means, but for practical purposes the history of the patient's trouble generally enables one to determine whether more than one flesh-containing meal is advisable. In most cases it suffices to allow a moderate amount of animal protein with breakfast and a fairly substantial dinner in the evening—very little, if any, food, and certainly no flesh, being permitted in the middle of the day.

FIG. 1.

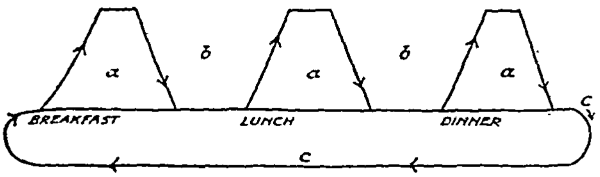

Diagram illustrating the rise and fall of waste products in the blood in the average type of metabolism—three flesh-containing meals a day being taken: (*a*) Metabolic period, (*b*) metabolic rest-period, (*c*) long metabolic rest-period during the night.

FIG. 2.

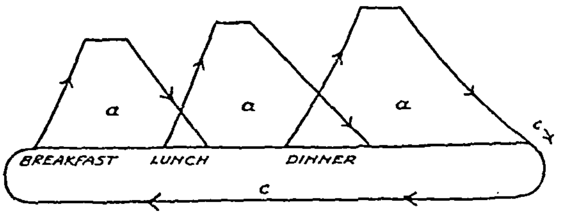

Diagram illustrating a slow metabolism, showing how the line of elimination crosses the line of rise of the waste products associated with successive meals. The diurnal metabolic rest-periods are lost and there is progressive accumulation of waste products in the blood. The nocturnal rest-period is shortened. (*a*) and (*c*) as Fig. 1.

Civilisation has doubtless had much to do with the weakening of those instincts in man which inform the lower animals what is unsuitable in the way of food. The senses of smell, taste, sight, and touch are keen advisers among animals. Human beings, on the other hand, suffer a good deal owing to the depreciation of these guides. Every now and then, however, we come across children in whom the instinct guides remain; children who dislike certain types of food, sometimes animal, sometimes vegetable. We have all come across children who dislike the traditional milk puddings, and become sick when forced to take them, or who do not like meat or fat. They are sometimes brought to us because they are supposed to be ill, the fact being that their natural instincts indicate that they have physiological inadequacies for the metabolism of the types of foods against which their tastes rebel. They are variants from the normal average, reversionaries perhaps towards the carnivorous or vegetarian types, as the case may be. The starch dyspepsias in some cases have this explanation, and how often are they treated by giving those remedies which are likely to aid the digestion of the food element which they require in lesser rather than increased amounts.

I am not dealing now with rare anomalies of metabolism but with those we encounter in our daily work.

INTERSEXUALITY IN ANIMALS.

Of all metabolic problems there are none quite so puzzling as those which seem to depend on sexual aberrations; cases in which males present some degrees of femininity or where females have or come to possess male characteristics. These cases are not uncommon, and they develop at varying periods of life. In the human being they do not attain to the extreme degrees referred to by Goldschmidt in his writings and recent addresses in this country, or by Dr. Crewe's hen which became a cock and, after doing its duty as a layer of eggs and a mother, eventually became the father of a family.

Preponderance of sex does not mean that there may not be present some degrees of intersexuality so far as hormone influences are concerned. It seems perfectly clear that the determination of sex takes place at the time of fertilisation of the ovum—that is, that if the X chromosome of the sperm unites with an X of the germ the offspring is female, whereas a union of chromosome Y male with the X female results in a male; but this does not imply that there may not be subsequent intersexuality due to the inheritance possessed by every individual, whether male or female, of hormones belonging to both sexes. There are dominant hormones belonging to and ruling the sex of the individual, and subdominant (or latent) ones of the opposite sex. The fact that mixed sex phenomena occur has, of course, been recognised for long—we are not unfamiliar with them in our clinical work—but the scientific study of intersexuality and its relation to sex determination has been largely carried out by a school of which Goldschmidt is representative. For my own knowledge of it I am largely indebted to his work as translated by Prof. Dakin,[2] whom I freely quote. It has been shown that in the animal kingdom there are two groups which are distinguishable from one another so far as determination of the sex characters of the individual are concerned.

1. Among the insects (moths, caterpillars, &c.) sex and everything appertaining to it is fixed at the time of fertilisation. Every cell of the body is then determined sexually, and there is no possibility of one part of the body being influenced by another. This has been proved experimentally, both by destruction of the sex organs and also by their transplantation, male to female and vice versa, both in the embryonic state of the insect and later. In neither case has any influence or change been produced in the secondary sex characteristics of the adult. Evidently the sex organs and the bodily structures which characterise the sex are quite independent of one another.

2. In the mammals, birds, &c., on the other hand, the distinctive characters are influenced by the presence of the

---

[2] Mechanism and Physiology of Sex Determination by R. Goldschmidt, translated by W. J. Dakin. 1923.

secretion of a ductless gland—i.e., there is a central organ which produces the hormones (and controls others) which are necessary for the completion and maintenance of the sex determination. There are no longer the independent activities of the individual cells throughout the body, but a coördinated and regulated development of sex characteristics, whether male or female, which is brought about by the activity of a secretory centre, situated in the reproductive organs. Castration experiments, such as those made in insects, are therefore very different in their results. In place of no change taking place in the secondary sex characteristics of the individual, the removal of the essential internal secretions brings about a modification or a disappearance of the characters of the sex, whereas, on the other hand, transplantation of the organs of the opposite sex results in the production of the secondary sexual characteristics of that sex.

Intersexuality in the first (insect type) group is therefore zygotic and entirely determined at fertilisation. Intersexuality in group 2 (mammal type) is hormonic and dependent for its development on the influence of internal secretions acting after fertilisation.

Hormonic Intersexuality in Man.

That hormonic intersexuality exists in man there can be no doubt. We know it from the effects of castration after the period of childhood (I shall refer presently to conditions coexistent with the arrest of development of the sexual hormone produced in the child). for it must be understood that intersexuality the result of castration only influences those organs or parts which develop, or are capable of developing, after the operation. The general result is that they approach the female type. The distribution of the pubic hair and the non-development of the beard point in this direction, and also the mammary gland and broad nipples and areolæ may develop. In other words, some degree of intersexuality has existed, and the already present but subdominant female hormones exert their influences upon these parts which have possibilities of differentiation when what would have been the dominant male-producing hormones are removed. We have clinical evidences of the same kind in women also. This relationship of the sex hormones can be best explained by means of a diagram (Fig. 3) on the lines of one in Prof. Dakin's book. The curves represent the hormone factors and I would direct attention to Goldschmidt's statement in relation to them, that a high concentration of one of the two hormones is not alone decisive for the production of pure sexes: a minimum of difference between the two is necessary. The dotted lines are curves of male hormones in different grades of female intersexuality showing how the male hormones may approximate the female ones and finally cross them. At (*a*) the diagram shows how the male line may cross the female one temporarily. This is a very complex subject and has interested me because many years of clinical observation have suggested that not a few disorders depend upon incoördinations of function which are brought about by mixed or approximating sexual metabolism. Some of these begin early in life and some later on: I rather think that in the main they become manifest at one or other of the climacteric periods. I have met with a case of a boy, aged 14, who presented a well-marked secondary anatomical characteristic. He had a unilateral female breast. So far no pathological phenomena have presented themselves, and he is quite boyish in his propensities.

FIG. 3.

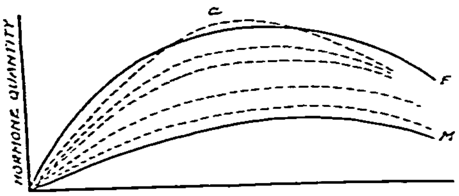

Diagram illustrating the relationship of the male to the female hormonic curve in the case of a female. The dotted lines indicate how the male curve may approximate the female one, or temporarily cross it at (*a*).

Ateleiosis.

The degrees of intersexuality are very variable. There are evidently cases which may be regarded as neutral, or in which the sex dominance is delayed at all events until a late period of life. We have an example of this in that very interesting variety of dwarfism designated ateleiosis (not arriving at perfection) and defined by Dr. Hastings Gilford.[3] It is characterised by conspicuous delay of growth and retardation of development; not necessarily an absolute arrest, because both may simply be very retarded. The subjects of it are not hermaphrodites externally. The sex is determined, but the hormone influences are arrested. For instance, the person may grow very slowly even up to the age of 30 or later, long after the normal period of growth has been passed. The point about these cases is that they are normally proportioned little people who have simply stopped growing at a normal rate during the period of childhood. They are the Peter Pans of real life. They retain the characters of childhood during the years when they should be adolescents or adults, or even until quite old. Sometimes the retardation begins during fœtal life, as in the well-known case of the Sicilian dwarf, who was only 7 inches long when born at the full time, and was 19½ inches tall when she died at 9 years of age. Her sexual organs (ovaries, uterus) and her bladder resembled those of a four months fœtus—i.e., the time when the arrest of her development probably began. Her ossification and dentition were those of a 2 years old child, but her proportions were perfect, and she was not deformed. General Mite, who died at the age of 41, was 31⅜ inches high, and weighed 14½ lb., was another of these antenatal cases. His sex organs remained quite infantile.

Cases of Ateleiosis Beginning Postnatally.

Commoner are those varieties of ateleiosis which begin postnatally. They generally grow normally until the second year or later childhood. I recently showed some of these cases in Liverpool, among them—

> A boy, who developed normally until his fourth year, when he ceased to grow at the normal rate, and is now in his twelfth year developmentally a child of 5. His height is 3 feet 6 inches, weight 3 st. 8 oz. Radiographs of his bones show that the centres of ossification are those of a child of 5 years old. He is bright and intelligent and in the seventh standard at school.

The following case I have had under observation for the longest period.

> A male, aged 40, grew normally until 7 years of age, then very slowly until 10, and after that hardly at all for a number of years. At 14 he stood 3 feet 10 inches, and weighed 3 st. 10 lb. He had then the appearance and development of a properly proportioned boy of 8. He was a bright, clever, and intelligent little boy, and a lady presented him with a toy cart and horse which amused him a good deal. He remained in this childish condition with little augmentation of height, but with childish sex organs and no pubic hair, until 22 years old, when he began to grow (after being dosed with thyroid substance), and he went on growing for three or four years until he measured 4 feet 10 inches at about 30 years of age. During the past 10 years he has gained nearly 2 inches and is now just under 5 feet high. He still has the face and rounded limbs of a young boy, but, strange to say, his sex organs began to develop two or three years ago. He has grown some pubic hair and the rudiments of a beard and moustache which he shaves about once a fortnight, and he has also manifested some virility. He has the female pubic distribution and rather prominent breasts. Evidently the curves of the sex hormones have slowly risen, the male are dominant, the female not far distant: a strange example of growth and development going on into middle life.

---

[3] Disorders of Postnatal Growth and Development.

These interesting cases illustrate a neutral type of sex metabolism. Ateleiotics are almost always cheerful and intelligent, and possessed sometimes of a great sense of humour. Their retained childishness is sometimes associated with a liking for the games of the young. It is interesting that they are said never to become bald even if they live to be quite old (there is a case recorded who lived to the age of 98), and certainly my cases just related have fine heads of hair. Cases of well-grown males presenting intersexuality have this same characteristic. Subjects of ateleiosis are much sought after for purposes of shows. In a juvenile troupe which I inspected some time ago the comedian of the party was upwards of 20, although he had the appearance of a little boy. Neutrality of this kind is not so distressing in its result as are those intersexualities which bring about their effects at a later period of life. There are some cases often classed as adolescent neurasthenics or as being hysterical which belong to this category.

I have recently seen a youth, aged 16, tall and effeminate-looking, with cold, blue extremities and rather poor physical development, who has quite definite indications of femininity in his prominent mammary areolæ and follicles, his undeveloped sexual organs, and female distribution of the pubic hair. His thyroid, too, is large and from time to time fluctuates in size. His thymus shadow (X ray) is also large. Here surely the subdominant female hormone curve approximates the dominant male one.

There are certain epileptics of both sexes who possibly come into this same class. Some time ago I saw a man, aged 30, who began taking fits at the period of puberty. They were suggestively periodic, occurring at monthly intervals, and he, too, had these prominent and broad mammary areolæ, little growth of facial hair, and the female pubic distribution was well marked.

The sexual hormones have so well-known an influence on the nervous system that it is not wonderful that psychoses and neuroses should be associated with a clash brought about by their incoördination. Two cases have left an indelible impression on my mind with reference to this.

The first was an adolescent girl who since puberty had developed a degree of melancholia with delusions of fear. She had the usual blue, cold extremities, slow breathing, and general apathy so common in these cases. Menstruation was not in abeyance, but she was always worse at these times, and had on one occasion threatened suicide. This girl had a large growth of downy hair on the sides of her face and on her lips and chin, and a marked triangular male distribution of the pubic hair. Here, again, the curve of the subdominant male in the individual was running high, and had perhaps overtaken the dominant female one, and there can be little doubt that the psychic disturbance was a corollary to this fact.

The other case was a young man of about 23 presenting female attributes. He had a rather soprano voice, no facial hair, the female pubic distribution, and prominent nipples. He had one small testis, the other being undescended, and he presented the nervous temperament and the cold, blue extremities which seem to be associated with incoördination of the sexual hormones.

GASTRIC ULCER AND INTERSEXUALITY.

I have often wondered whether gastric ulcer is in any way related to an intersexuality perhaps with temporary crossings of the female curve by the male one. It is one of those diseases which we rather tend to look upon as an entity, but I think there are reasons for believing that the ulcer is a local manifestation of a constitutional condition. Duodenal ulcer is essentially a male disease; the perforating gastric ulcer attacks the female. Is there any explanation for this? Possibly some light may be thrown upon it by a careful analysis of its symptoms, not those appertaining to the ulcer itself but the ones which lead up to it. It will almost always be found that a considerable change takes place in the constitution of the patient. Sometimes this change occurs at or about the climacteric period of adolescence, but at all times it is reminiscent of some of its accompaniments. If a girl is observed who is passing through this period it can often be noted that the ruddy cheeks and robust habit of body, the warmth and activity of the child, give place to a tendency to blueness and lividity. The thyroid becomes enlarged, sometimes greatly so, in its effort to supply secretion. The face and extremities look cyanosed and the latter are cold. Apathy and syncopal attacks are not uncommon accompaniments. This is related to an, as yet, unestablished balance in the sexual hormones. Vascular spasm is characteristic. Now inquire into the history of a case of gastric ulcer and observe the resemblance. These patients almost invariably start their trouble with somewhat similar phenomena: coldness and blueness of the extremities, heliotropic complexion, coldness and not infrequently cramps in the hands and feet. If menstruation has previously been established there is frequently amenorrhœa. Then comes the indigestion: not pain after food, but a feeling of weight and fulness indicative of deficient enzyme secretion, and at last the ulcer, a little punched-out affair without surrounding thickening or inflammation. The pain characteristic of the chronic phase of gastric ulcer is a later symptom corresponding to the period of subsequent inflammation. The prodromal symptoms are those of vascular spasm like those of the climacteric. If in the female the subdominant male curve approximates the dominant female one, or temporarily crosses and recrosses it, it is quite conceivable that the results I have described might follow and an explanation be found for a perplexing trouble. The hypothesis is worth thought, especially since the administration of thyroid gland often remedies the prodromal conditions, including the amenorrhœa if it be present. I always give thyroid in gastric ulcer both during treatment and for some time after recovery.[4]

I have only one thing more to add about inherited sex metabolism in relation to disease. Over a period of 18 to 20 years in my large children's out-patient clinic I have been noting the colour of the children's eyes and some other attributes in relation to those of their parents, and it seems pretty clear that in a given generation reciprocal criss-cross inheritance is commoner than linked sex inheritance. That is to say, a girl tends to inherit her father's attributes, a boy his mother's. If a father is blue-eyed and the mother brown-eyed the sons are often brown-eyed and the daughters blue-eyed. A tall father and a small mother tend to produce small sons and tall daughters. It is this principle which has given rise to a truism that if a man wants to have clever sons he must take care to marry a clever woman. There are plenty of exceptions, but this form of inheritance is common enough to make it noticeable. Departure from this order of things is occasionally associated with some degree of intersexuality; for instance, I recently saw a well-developed girl, aged 15, suffering from asthma which began in childhood and became worse at puberty. She was a dark-haired girl with blue eyes; she tended to be hirsute about the lips and presented some other intersexual characters—e.g., triangular pubic hair. She was the blue-eyed child of a dark-complexioned and dark-eyed father and had inherited her mother's blue eyes and other characters (including asthma by the way) as though she had been intended for a boy—a confusion of hormonic coördination. This, however, is debatable ground, and there are Mendelian factors at work in this realm of inheritance.

Hypothesis based upon observation has led me to a consideration of these metabolic variations and imperfections and of their association with flaws in the balance of our bodily chemistry which may account for some of the disorders which we encounter in our everyday experiences.

---

[4] Since the above was written, a man, aged 21, has been under observation in the Royal Southern Hospital presenting the clinical signs of gastric ulcer and with a history of the prodromal symptoms referred to. He was of fair complexion, had a girlish face, no signs of facial hair. The mammary areolæ broad with prominent nipples. Female distribution of the pubic hair. Testicles small. The bodily contour not masculine. This case, presenting signs of gastric ulcer, confirms the hypothesis that this disease may be related to intersexuality.

THE CELLULAR CONTENT OF MILK: VARIATIONS MET WITH UNDER PHYSIOLOGICAL AND PATHOLOGICAL CONDITIONS.*

By P. C. VARRIER-JONES, M.A.CAMB., M.R.C.S.,
MEDICAL DIRECTOR, PAPWORTH VILLAGE SETTLEMENT,
CAMBRIDGE.

(*With Coloured Plate.*)

Introduction.

OF late years increasing attention has been given to the consideration of milk-supplies from the public health point of view, and the old standards, depending largely upon the senses of taste and smell, and the relative proportions of solids and cream, on specific gravity and opacity, are no longer regarded as the ultimate basis for a proper judgment as to the quality of milk. Various new methods have been introduced, especially in America, for the purpose of controlling the character of these supplies. These have for the most part been directed to the determination of two different sets of conditions: (1) The number of micro-organisms present in milk; (2) abnormal constituents in milk arising from the condition of the udder. Obviously both problems are intimately related and cover wide fields; in this paper the latter only is investigated.

American observers, attacking the problem of the cellular content of milk from the purely quantitative point of view, have formulated standards for milk inspection by which practically whole herds have been condemned; on their standards as many as 90 per cent. of a herd were condemned for producing milk which was supposed to contain pus. Such an example illustrates the chaotic state of our knowledge of the nature and source of these cellular elements of milk. At present there is no general agreement as to: (1) The nature of the cellular elements of milk; (2) the origin of such elements; (3) the significance of the presence of various types of cells; (4) the part some of these cells play in the physiological process of milk production; (5) or their significance in the various pathological processes which may occur in the cow's udder. To elucidate these problems the present work has been undertaken.

Among the difficult problems of modern dairying, still remaining unsettled, is that of the significance of the cellular elements and micro-organisms that occur in milk. On these there exists the greatest divergence of opinion, even on what appear to be the simplest questions.

W. G. Savage,[1] writing on this subject, remarks very pertinently, "That milk should not contain pus." Few will deny this, but what constitutes pus in milk? All milk contains leucocytes, but do these leucocytes become converted into pus cells, and if they do how can one be distinguished from the other? The presence of a certain number of leucocytes in milk is strictly physiological, though, beyond a certain point it may, probably does, become a pathological feature. What, then, are the bounds to be set to our characterisation of these conditions? One school holds firmly to the idea that the cellular contents of milk are all derived from the blood; that they are true blood cells, and that under certain conditions they constitute pus. Another school as firmly denies the above proposition, and asserts that the cells of milk are tissue cells of purely epithelial origin which under no circumstances can be spoken of as pus cells. As in most similar problems, the truth, as I hope to be able to demonstrate, appears to lie somewhere between.

Methods of Procedure and Examination Used in this Investigation.

These must include a method of staining which would enable the observer to distinguish the various cells that may be present. Any method which fails to include this fails, in my opinion, in its entirety. The extraordinarily divergent results described, the contradictory statements made, and the confusion which exists in the literature of the subject, are due the failure of most observers to recognise and to appreciate this elementary condition.

The cells found in milk are many and of various types. Their presence in normal milk undoubtedly must indicate, and be a measure of, the various changes which occur in the secretory tissue and ducts of the milk gland during the physiological secretory process. Given a certain physiological condition of the udder an appropriate cell indicating that condition will make its appearance in the milk. Given a pathological condition of the milk-ducts or acini, and again amongst the solid contents of the milk certain cells must predominate. The use of any method, therefore, which fails to differentiate these various cells must lack the one thing essential for our purpose. Miller[2] says: "As regards leucocyte and pus cells there is no intrinsic difference. A leucocyte in fluids other than blood plasma, as milk, for example, soon undergoes changes which render it indistinguishable from a pus cell." The oft-quoted statement of Savage,[3] that he cannot differentiate between a leucocyte and a pus cell is, undoubtedly, true so far as the comparatively few isolated cells of a clean milk are concerned, but not when applied to a large percentage of cases.

The appearance of a high cell count due to some physiological process—if we are unable to distinguish this cell from one which predominates in a pathological condition—may lead us to pronounce the udder diseased in cases in which no disease exists. The want of a method such as that above described, where alterations in the cell count have taken place, has often given rise to statements of which the following is a typical example :—

> "It was not surprising, therefore, when making consecutive observations on a carefully watched herd, to find that a cow which throughout her whole period of lactation had given a milk low in leucocytes, should suddenly develop pus, and that such a development indicated the close of her milking period. In almost 75 per cent. of the herd, perfectly healthy, clean cows show pus at the close of the milking period; and a coincident chemical analysis indicates that the percentage of butter-fat is from 0·5 to 1·5 per cent. above the normal for that particular individual. Such a condition is interpreted as indicating the termination of lactation, and accordingly the cow is at once dried off with, apparently, advantage to both herself and her calf."[4]

I hope to be able to show that although the cell count is increased in milk taken from a cow which is drying off, the condition is entirely physiological and certainly not pathological. Had the cells been properly stained with a differential stain, such a mistake could scarcely have been made. The important feature in the method I have used is that it consists essentially in a differential cell count, the cells being distinguished, counted, and classified according to their morphological characters.

An accurate knowledge of the characters of the various cells found in milk is essential for a differential count. My observations lead me to give the following cells as those to be found in milk obtained from a normal animal.

1. *The Finely Granular Eosinophile Cell.*—A polymorphonuclear cell, more or less round or elliptical or even irregular in outline, the shape depending on various factors, such as the length of time which is allowed to elapse between milking and the examination and the speed at which the milk is centrifuged.

The cytoplasm is clear, and remains unstained by Jenner's method, the whole being filled with very fine granules which stain a brilliant pink.

The nucleus, as a rule, stains a deep blue; unless the cell is old, or degenerated, when it stains badly. It may be branched or lobulated, the lobes being held together by fine chromatin threads. In nearly all the cells of this type the nucleus is seen to be formed of a thick chromatin network, some parts of which take the stain much more readily than others.

The size of the cell: The size varies between 10–12 μ in diameter. In the cells of fresh milk, examined immediately, pseudopodia stretch out from these cells in all directions, while even in many samples of commercial milk the cells are seen to be distinctly phagocytic—the bacteria being contained in vacuoles lying in the substance of the cell. (See Fig. I.) In other samples of commercial milk these cells often break down, and stain badly, the nucleus protruding through the cell cytoplasm. Crowds of bacilli may often be seen surrounding them.

---

* This investigation has been carried out on behalf of the Medical Research Council.

This polymorphonuclear cell is constantly found in milk. In a normal sample the number is very small, almost negligible; but in milk from an inflamed quarter, the number may be very considerable. Fig. II. (cow 9, L.H.Q.) shows a film prepared from the deposit of milk taken from an acutely congested udder, the result of sending the cow to market with an abnormally full udder. In view of this custom of farmers and dairy owners too great stress can scarcely be laid on this point.

2. *The Coarsely Granular Eosinophile Cell.*—The coarsely granular eosinophile cell is slightly larger than the finely granular polymorphonuclear cell, it is oval or round in shape, and measures 10 to 13 μ in diameter. The cytoplasm is perfectly clear and transparent, but in this case again is closely studded with highly refractile granules, measuring in some cases as much as 0·5 μ in diameter; by Jenner's method these granules stain a deep pink.

The nucleus, usually of a light blue tint, is placed either in the centre of the cell or, more commonly, towards the periphery. It is either kidney-shaped or lobed, the different lobes being connected by bands of nuclear substance. In many films the cells appear to have burst; the granules are then scattered in all directions.

3. *The Large Mononuclear Leucocyte.*—The large mononuclear leucocyte is one of the largest cells met with in the deposit from cow's milk. It is round or oval in shape, invariably staining a dark blue. The stain, however, is not evenly distributed, but appears as a tangled thread throughout the substance of the cell. This is the nucleus which fills up nearly the whole of the cell. Usually, however, there is a small portion of cytoplasm on one side of the nucleus, but it rarely makes a complete circle round it. This portion of the cell is stained less darkly, but it is nevertheless of a distinct blue colour. These cells are invariably present in all samples of cow's and goat's milk, and in some are a very prominent feature. (Fig. III.)

4. *The Lymphocyte.*—The lymphocyte is a small blue cell which, as a rule, stains deeply. The cytoplasm is small in amount and forms a thin ring of light blue colour around the darkly-stained nucleus. These cells vary in size from 2 to 4 μ, the majority measuring about 3 μ. The nucleus is round or slightly oval in shape, stains darkly, and is not reticular. It occupies almost the whole of the cell. Such cells are fairly numerous in normal milk, but appear to be found in greater numbers in certain breeds of cattle than in others. (Fig. IV.)

5. *The Basophile Cell.*—The basophile cell (8–10 μ), a rare cell, is almost circular in shape, but may be oval. The cytoplasm is clear and transparent, and has scattered unevenly throughout its substance dark blue granules, large and small. The large nucleus occupies two-thirds of the cell, it is oval or rounded, and is always single. By Jenner's method it stains a pale blue. As a rule, the basophile cell is absent from films of normal milk, but under certain conditions it appears, though never in great numbers.

6. *The Large Neutrophile Cell* (5–9 μ).—The large neutrophile cell is extremely rarely met with. It is oval in shape, rarely round. The cytoplasm is stained a faint light blue throughout, the whole being filled, except in the region of the nucleus, with very fine granules, which take on a pale mauve tinge. By Jenner's stain the nucleus is tinged light blue.

7. *Red Blood Corpuscles.*—Red blood corpuscles are invariably present in a sample of cow's milk. In normal milk they are exceedingly few in number; as a rule, only one or two are found in a film made from the deposit of 10 c.cm. of milk. It must be remembered, however, that in milk films the individual red blood corpuscles are not exactly similar to those found in normal blood, but they are always easily recognisable.

8. *Large Epithelial Cells.*—Large epithelial cells are almost always present. They vary greatly in size, some measuring as much as 20 μ in diameter. The cytoplasm is somewhat granular, having a ground-glass appearance; it stains a more or less deep blue with Jenner's stain. The cells are usually rounded, but may be oval, and appear to have a well-developed envelope, which takes on a slightly deeper stain. The nucleus is large, oval or rounded, occupying a quarter of the cell, and stains a less deep blue than the rest of the cell. It usually has a mottled appearance as though composed of a chromatin network. In the cytoplasm of the cell are usually one, two, or even more clear spaces with well-defined outlines, usually round, more rarely oval in shape. These are fat globules surrounded by an envelope which prevents the fat from taking the ordinary fat stains.

9. *Mononuclear Eosinophile Cell.*—Other vacuolated cells appear from time to time in milk. Apart from the finely granulated eosinophile cell which may become vacuolated through age, or otherwise, there are other cells which closely resemble them. The cytoplasm of these cells, instead of being clear and transparent, stains a light pink, the substance being more or less vacuolated. The nucleus stains a light blue and is usually pushed to the side of the cell by the large number of vacuoles in the cytoplasm. These cells are abundant, especially when the cow dries off; but they may be present at other times. They may, however, be unvacuolated, when they may measure 9–10 μ in diameter, but they are often less than this. I regard this as an epithelial cell, probably derived from the secretory layer of the gland tissue. (Fig. V.)

The vital objection which can be urged against many methods of investigation is that all the cells are considered and counted as leucocytes. Obviously, in some cases of mastitis, in which the majority of the cells are of the polymorphonuclear type, the resulting count will be correct; but in more chronic cases, or in other conditions when these cells do not predominate, the methods break down, and can have little practical use.

Method of Cell Examination Adopted.

The method of cell examination adopted in this inquiry is essentially a differential count method, and a stain is used which has been found to give constant and reliable results. The procedure is as follows:—

The animal is milked in the ordinary way and at the usual times. During the milking three samples of the milk from each quarter—12 samples in all—are milked direct into sterilised test-tubes, which are plugged immediately. Of the three samples one is taken at the commencement of milking—called the "fore-milk"—another in the middle of the operation—the "middle-milk"—and a third at the end of milking (but without any undue straining)—the "strippings." Taking each of these samples in turn the tube is well shaken and 10 c.cm. poured into a centrifuge tube of Houston's pattern, the lower part of which is drawn out and accurately marked with a scale of 1/100 cm., and centrifuged at 3000 revolutions per minute for ten minutes. The cream and supernatant fluid are carefully removed, 0·5 c.cm. of milk being allowed to remain above the deposit. These are thoroughly mixed with a capillary pipette on which is a bulb and into which the mixture is finally drawn up. The pipette is then sealed off and centrifuged until the deposit is carried to the bottom of the pipette, whence with a still finer tube it may be removed and spread on a glass slide. The film is then air-dried, stained at once by Jenner's method, examined with a Zeiss 1/12, and the cells noted, described, drawn, and counted.

This method is not put forward as giving correct numerical results, but rather as a differential method in which the well-stained cells of different types may be readily distinguished.

The question now arises, are all the cells thrown down as sediment in the centrifuge, or are some carried upwards and held in position by the cream which rises to the surface? In normal milk I have found that the number of cells entangled in the cream is a negligible quantity, and it is necessary in any differential count to examine only the deposit found at the bottom of the pipette.

Cellular Content of Normal Milk.—Taking a sample of milk from any quarter of the udder of a cow selected at random one is struck at once by the variety of cells met with. Should the cow happen to be a normal animal—e.g., a heifer some days after her first calf, without any complications or udder trouble after calving—the blue cells, both large and small, which occupy the field are numerous, and at once arrest attention: indeed, one is apt to make up one's mind that the milk is full of lymphocytes both of the large and small variety. Looking over the fields one may observe here and there, not usually more than one per field, a finely granular eosinophile cell, with nucleus sharply stained, and with the granules distinctly visible; characters that enable one to pick it out without difficulty from the surrounding cells. It would be a great mistake, and very misleading, to class these cells together as pus cells; most of them are broken-down polymorphonuclear cells. Now and again a coarsely granular eosinophile cell which stains well, resembling very closely the coarsely granular eosinophile cell of ox's blood, may be seen. Again, a much larger cell, round or oval in shape, with large pale blue nucleus, the cytoplasm of the cell staining a mottled blue, may be present. Evidently these different cells cannot be lumped together as pus. Moreover, one finds in the field a number of small dots, stained deep blue, 1μ or so in diameter, sometimes with only a tag of pink substance around the blue point, or near its edge. These are obviously nuclei extruded, possibly, from blood cells, but more probably from secretory epithelial cells of the acini. The pink portion is part of the cytoplasm of the cell which was torn away when the nucleus was extruded. From this picture, which is invariably presented in the sediment from normal milk, it is obvious that a simple count can give no information as to the condition of the secreted fluid or of the secretory tissue. The number of cells (lymphocytes), added to the stray polymorphs, coarsely granular eosinophiles and tissue cells, along with the extruded nuclei, may give a high "leucocyte" count; but under these circumstances we cannot justly claim that the cow is suffering from a diseased condition of the udder or that the fluid is "pus." A differential count of cellular deposit *must* always be made before a diagnosis is justified.

Cellular Content of Abnormal Milk.—A high cell count is not of necessity evidence of a diseased udder, nor, on the other hand, does a low count necessarily indicate an udder free from disease. The actual count may, of course, in certain doubtful cases help in the formation of a diagnosis, but it cannot by itself be depended upon. For the present I insist simply on the point which I consider to be of vital importance in all cytological examinations of milk, the necessity of applying this differential staining and counting method *quarter by quarter;* for it is not sufficient to make an examination of the mixed milk by this method.

Physiological Conditions Influencing Cellular Content of Milk.—Any physiological influence which may affect the secretion of milk will also probably influence the cell-content.

Breed of Cow.—Other things being equal, such as age of cow, time which has elapsed after calving, &c., it appears that normal cows of different breeds have different proportions of cells in their milk; a thoroughbred Hereford (Fig. IV.) gives a cell-content of the milk which differs from that obtained from a thoroughbred Shorthorn (Fig. VI., L.F.Q.), and these, again, both differ slightly from the cell-content of the milk of a Welsh heifer. In the Hereford heifer the cells are of large mononuclear lymphocyte type. Large mononuclear leucocytes also appear to be present invariably in the milk from Hereford cows, but are not so noticeable a feature in the films prepared from the milk of the cows of the other breeds. The Welsh heifer's milk always contains many—indeed, they were almost the most noticeable feature—of the very small blue cells, which are almost entirely absent from the Hereford cow's milk. Owing to the large number of these small cells, the cellular content of the Welsh heifer's milk is always high. In the milk of the Shorthorn, the very small cells so familiar by their presence in the milk of the Welsh heifer are here seldom met with: their place is taken by cells with a pale-blue nucleus and a surrounding layer of granular protoplasm, the granules being very fine and staining blue. This divergence of cellular content still requires explanation.

Influence of Calving on Cellular Content.—It is well known that the colostrum obtained from the udder immediately and for a definite time after the cow has calved, differs very considerably from ordinary milk in its chemical composition, in its fat ratio, and in its cell content. It is yellow and viscid, has a strong odour, and coagulates on boiling. Besides the colostrum corpuscles—i.e., cells laden with fat globules probably derived from the epithelium of the acinus the polymorphonuclear cells are very numerous, some staining sharply, others vacuolated and evidently in process of disintegration. These colostrum corpuscles appear in such great numbers that the stained film appears quite pink, in this respect differing markedly from the film of the ordinary milk, which has a blue tinge. Lymphocytes, both of the large and small variety, though present, are not numerous; the cell with the pale-blue nucleus and granular protoplasm (with fine blue granules) predominates. The polymorphs, even in colostrum, are actively phagocytic. As the milk becomes normal the colostrum corpuscles and the polymorphonuclear cells gradually disappear; and, if no inflammatory process supervenes, the milk cells soon return to their normal count. If, however, by any chance one quarter of the udder becomes inflamed, the polymorphonuclear variety of cell persists, and is present even when the milk from the other quarters affords no trace of its presence. When one compares films prepared from milk yielded by a cow a day or so after calving with those of normal cows—e.g., Shorthorn. Clara, Hereford, and Welsh heifer—one is struck by the difference of cellular content. The colostrum corpuscles gradually diminish in number, become less distinct, and disintegrate. The polymorphonuclear cells in colostrum stain well as a rule; but towards the third or fourth day these also show active signs of disintegrating. The blue cells—the lymphocytes—are prominent throughout the whole period of colostrum production, and continue present during the transition period.

Effect of "Stage of Milking" on Cellular Content.—The first milk drawn off, usually spoken of as the fore milk, is the fluid which fills up the teat canal and the milk sinus, and usually contains fewer cells than the milk drawn off later. The sediment left in the tubes in the various centrifuge samples is, as a rule, greatest in the strippings, and one is inclined to generalise and to say that the greatest number of cells is present in these strippings. This, however, is not invariably the case.

As a rule, unless a method of milking such as the use of a milk tube is employed, the cells of all three samples are much the same as regards both type and proportion, although the absolute number may vary considerably.

Effect of Time of Milking and Intervals between this Operation on the Cellular Content of Milk.—If the interval between the morning and the evening milkings be prolonged unduly the cells increase in number, especially the polymorphonuclear cells and the red blood corpuscles; the longer the interval between these milking periods the more the udder becomes distended; the vessels become very congested, and in extreme cases, although the milk may have been normal before the distension occurred, the stained films show masses of sharply stained normal polymorphs considerably in excess of what should be present in normal milk. Fig. II., cow 9, is from a film prepared from the sediment separated from the milk of a cow whose calf had been kept away from her during one night and part of the next day. The udder was greatly distended and yielded an abnormal quantity of milk, which presented no unusual appearance to the naked eye. Polymorphonuclear cells are seen in great numbers and appear to have retained their shape; the granules stain well, and the nuclei are distinctly lobed. Red blood corpuscles are also present in fair numbers, but there is a distinct paucity of the blue cells, both large and small. The conditions in this case were very remarkable, and were certainly due to the congestion following the long interval between milking.

Relationship between the Fat Content and Cellular Content of Milk.—In no case have I found any increase in the fat content of milk where there has been a rise in the polymorphonuclear cells. The statement made by Pennington and Roberts[4] that "in almost 75 per cent. of the herd, perfectly healthy, clean cows show *pus* at the close of the milking period and a *coincident chemical analysis*, that the percentage of butter fat is from 0·5 to 1·5 per cent. above the normal for that particular individual," is certainly not borne out by the results obtained during the present investiwhile even in many samples of commercial milk the cells are seen to be distinctly phagocytic—the bacteria being contained in vacuoles lying in the substance of the cell. (See Fig. I.) In other samples of commercial milk these cells often break down, and stain badly, the nucleus protruding through the cell cytoplasm. Crowds of bacilli may often be seen surrounding them.

This polymorphonuclear cell is constantly found in milk. In a normal sample the number is very small, almost negligible; but in milk from an inflamed quarter, the number may be very considerable. Fig. II. (cow 9, L.H.Q.) shows a film prepared from the deposit of milk taken from an acutely congested udder, the result of sending the cow to market with an abnormally full udder. In view of this custom of farmers and dairy owners too great stress can scarcely be laid on this point.

2. *The Coarsely Granular Eosinophile Cell.*—The coarsely granular eosinophile cell is slightly larger than the finely granular polymorphonuclear cell, it is oval or round in shape, and measures 10 to 13 µ in diameter. The cytoplasm is perfectly clear and transparent, but in this case again is closely studded with highly refractile granules, measuring in some cases as much as 0·5 µ in diameter; by Jenner's method these granules stain a deep pink.

The nucleus, usually of a light blue tint, is placed either in the centre of the cell or, more commonly, towards the periphery. It is either kidney-shaped or lobed, the different lobes being connected by bands of nuclear substance. In many films the cells appear to have burst; the granules are then scattered in all directions.

3. *The Large Mononuclear Leucocyte.*—The large mononuclear leucocyte is one of the largest cells met with in the deposit from cow's milk. It is round or oval in shape, invariably staining a dark blue. The stain, however, is not evenly distributed, but appears as a tangled thread throughout the substance of the cell. This is the nucleus which fills up nearly the whole of the cell. Usually, however, there is a small portion of cytoplasm on one side of the nucleus, but it rarely makes a complete circle round it. This portion of the cell is stained less darkly, but it is nevertheless of a distinct blue colour. These cells are invariably present in all samples of cow's and goat's milk, and in some are a very prominent feature. (Fig. III.)

4. *The Lymphocyte.*—The lymphocyte is a small blue cell which, as a rule, stains deeply. The cytoplasm is small in amount and forms a thin ring of light blue colour around the darkly-stained nucleus. These cells vary in size from 2 to 4 µ, the majority measuring about 3 µ. The nucleus is round or slightly oval in shape, stains darkly, and is not reticular. It occupies almost the whole of the cell. Such cells are fairly numerous in normal milk, but appear to be found in greater numbers in certain breeds of cattle than in others. (Fig. IV.)

5. *The Basophile Cell.*—The basophile cell (8–10 µ), a rare cell, is almost circular in shape, but may be oval. The cytoplasm is clear and transparent, and has scattered unevenly throughout its substance dark blue granules, large and small. The large nucleus occupies two-thirds of the cell, it is oval or rounded, and is always single. By Jenner's method it stains a pale blue. As a rule, the basophile cell is absent from films of normal milk, but under certain conditions it appears, though never in great numbers.

6. *The Large Neutrophile Cell* (5–9 µ).—The large neutrophile cell is extremely rarely met with. It is oval in shape, rarely round. The cytoplasm is stained a faint light blue throughout, the whole being filled, except in the region of the nucleus, with very fine granules, which take on a pale mauve tinge. By Jenner's stain the nucleus is tinged light blue.

7. *Red Blood Corpuscles.*—Red blood corpuscles are invariably present in a sample of cow's milk. In normal milk they are exceedingly few in number: as a rule, only one or two are found in a film made from the deposit of 10 c.cm. of milk. It must be remembered, however, that in milk films the individual red blood corpuscles are not exactly similar to those found in normal blood, but they are always easily recognisable.

8. *Large Epithelial Cells.*—Large epithelial cells are almost always present. They vary greatly in size, some measuring as much as 20 µ in diameter. The cytoplasm is somewhat granular, having a ground-glass appearance; it stains a more or less deep blue with Jenner's stain. The cells are usually rounded, but may be oval, and appear to have a well-developed envelope, which takes on a slightly deeper stain. The nucleus is large, oval or rounded, occupying a quarter of the cell, and stains a less deep blue than the rest of the cell. It usually has a mottled appearance as though composed of a chromatin network. In the cytoplasm of the cell are usually one, two, or even more clear spaces with well-defined outlines, usually round, more rarely oval in shape. These are fat globules surrounded by an envelope which prevents the fat from taking the ordinary fat stains.

9. *Mononuclear Eosinophile Cell.*—Other vacuolated cells appear from time to time in milk. Apart from the finely granulated eosinophile cell which may become vacuolated through age, or otherwise, there are other cells which closely resemble them. The cytoplasm of these cells, instead of being clear and transparent, stains a light pink, the substance being more or less vacuolated. The nucleus stains a light blue and is usually pushed to the side of the cell by the large number of vacuoles in the cytoplasm. These cells are abundant, especially when the cow dries off; but they may be present at other times. They may, however, be unvacuolated, when they may measure 9–10 µ in diameter, but they are often less than this. I regard this as an epithelial cell, probably derived from the secretory layer of the gland tissue. (Fig. V.)

The vital objection which can be urged against many methods of investigation is that all the cells are considered and counted as leucocytes. Obviously, in some cases of mastitis, in which the majority of the cells are of the polymorphonuclear type, the resulting count will be correct; but in more chronic cases, or in other conditions when these cells do not predominate, the methods break down, and can have little practical use.

Method of Cell Examination Adopted.

The method of cell examination adopted in this inquiry is essentially a differential count method, and a stain is used which has been found to give constant and reliable results. The procedure is as follows:—

The animal is milked in the ordinary way and at the usual times. During the milking three samples of the milk from each quarter—12 samples in all—are milked direct into sterilised test-tubes, which are plugged immediately. Of the three samples one is taken at the commencement of milking—called the "fore-milk"—another in the middle of the operation—the "middle-milk"—and a third at the end of milking (but without any undue straining)—the "strippings." Taking each of these samples in turn the tube is well shaken and 10 c.cm. poured into a centrifuge tube of Houston's pattern, the lower part of which is drawn out and accurately marked with a scale of 1/100 cm., and centrifuged at 3000 revolutions per minute for ten minutes. The cream and supernatant fluid are carefully removed, 0·5 c.cm. of milk being allowed to remain above the deposit. These are thoroughly mixed with a capillary pipette on which is a bulb and into which the mixture is finally drawn up. The pipette is then sealed off and centrifuged until the deposit is carried to the bottom of the pipette, whence with a still finer tube it may be removed and spread on a glass slide. The film is then air-dried, stained at once by Jenner's method, examined with a Zeiss 1/12, and the cells noted, described, drawn, and counted.

This method is not put forward as giving correct numerical results, but rather as a differential method in which the well-stained cells of different types may be readily distinguished.

The question now arises, are all the cells thrown down as sediment in the centrifuge, or are some carried upwards and held in position by the cream which rises to the surface? In normal milk I have found that the number of cells entangled in the cream is a negligible quantity, and it is necessary in any differential count to examine only the deposit found at the bottom of the pipette.

Cellular Content of Normal Milk.—Taking a sample of milk from any quarter of the udder of a cow selected at random one is struck at once by the variety of cells met with. Should the cow happen to be a normal animal—e.g., a heifer some days after her first calf, without any complications or udder trouble after calving—the blue cells, both large and small, which occupy the field are numerous, and at once arrest attention: indeed, one is apt to make up one's mind that the milk is full of lymphocytes both of the large and small variety. Looking over the fields one may observe here and there, not usually more than one per field, a finely granular eosinophile cell, with nucleus sharply stained, and with the granules distinctly visible; characters that enable one to pick it out without difficulty from the surrounding cells. It would be a great mistake, and very misleading, to class these cells together as pus cells: most of them are broken-down polymorphonuclear cells. Now and again a coarsely granular eosinophile cell which stains well, resembling very closely the coarsely granular

gation. The cells met with in drying-off cows appear to be epithelial in type and derived from the walls of the acini.

When these cells are present the fat content rises, whilst, as will be seen from the following experiment the fat content, instead of rising with the presence of pus, actually diminishes. A goat which was in full milk had one quarter of the udder injected with 10 c.cm. of an emulsion of streptococci before the time for evening milking, and was not milked until the following morning. Films were then prepared as described above, and the milk was analysed chemically. The yield of milk and the quantity of deposit (which in this case consisted entirely of cells and streptococci) and the amount of fat present are given in the following table :—

Fat Content and Cellular Content of Milk.

Date.	Amount of milk from—			Fat per cent.		Cell content.	
	Time of milking.	Right quarter.	Left quarter.	Right quarter.	Left quarter.	Right quarter.	Left quarter.
		c.cm.	c.cm.			c.cm.	c.cm.
Feb. 27	Morning	52·5	9·9	6·95	3·11	—	—
	Evening	25·0	4·8	6·75	3·46	0·02 in 2·5	0·5 in 2·5
,, 28	Morning	64·0	11·85	5·1	4·46	0·03 in 8·0	0·4 in 2·5
	Evening	23·0	5·1	6·0	5·99	0·03	0·2
March 1	Morning	77·0	17·0	5·4	4·95	0·05 in 8·0	0·2 in 5·0
	Evening	10·5	2·5	7·71	3·04	0·01	0·13 in 5·0
,, 3	Morning	98·5	19·0	4·3	2·09	0·05 in 3·0	0·03 in 3·0
	Evening	35·0	6·5	3·45	3·24	0·05	0·03
,, 4	Morning	101·0	21·0	3·5	3·25	0·05 in 3·0	0·03 in 3·0
	Evening	31·0	7·0	—	—	0·25	0·01

It will be seen that where, as in the normal quarter (R.Q.), the amount of milk produced and the deposit thrown down remained normal in amount, in the infected quarter (L.Q.), although the yield of milk was much reduced, the deposit was greatly increased; but that the fat content, though normal in the unaffected quarter, rapidly decreased in the quarter which had received the injection of streptococci and had the larger deposit; the larger deposit being due entirely to the enormous increase of polymorphonuclear leucocytes which had all the appearance of pus cells. As the quarter gradually improved and became normal, the deposit decreased, the cells of the polymorphonuclear variety became less numerous, and the fat content again approached normal. When in acute infections of the udder true pus is produced the fat content of the milk invariably falls.

Nervous Excitement.—Nervous excitement undoubtedly has a marked effect on the milk yield of cows, but I have been unable to observe any marked change in the cellular content of milk, such as may be attributed, solely, to this cause.

Physiological "Drying-Off."—"Drying-off" should be a perfectly natural physiological process, but in some cases it may be due to pathological causes. In the normal animal when drying-off occurs the increase in the number of cells comes on quite gradually; the milk yield slowly falls off, and with this there is a corresponding increase in the number of cells, especially of one definite type. The films all present common features, and with a little practice it is possible to make a diagnosis of drying-off with great confidence. Should no differentiation be made between the various cells the condition would be diagnosed as due to previous disease, probably chronic inflammation of long standing. These drying-off cells, however, are usually circular in outline; the cytoplasm, which is often "vacuolated," contains no granules, and takes on an irregular somewhat deep pink stain. The nucleus may be single, or may be bi- or even tri-lobed, with the lobes apparently not joined together. The one, two, or even more "vacuoles" present in a single cell are stained by Nile blue, and therefore contain fat. The condition is well shown in Fig. V. of red cow, R.F.Q.

Pathological "Drying-Off."—The drying-off process may, however, be due to some pathological condition. Any severe inflammatory trouble may result in drying-off of the quarter or quarters affected. The cells are then of several varieties, the polymorphonuclear form being found in equal or even greater numbers than those described above as usually present. The inflammatory process introduces an extra factor, and may alter the cellular content to such an extent that the deposit may now be described as pus. If, however, the quarter be not severely affected, and resumes its normal function, the natural drying-off process supervenes, and the cells characteristic of that condition predominate. accompanied, however, by some polymorphonuclear cells which remain as evidences of the inflammatory process.

Sterile Milk.—It is almost impossible, from a perfectly normal heifer, to procure a sterile sample of milk. I have attempted to obtain such a sample by adopting the following procedure: The cow was placed in a large operating theatre, the floor of which was kept moist with a 3 per cent. solution of lysol. The udder and flanks were then washed and kept moist with the lysol solution, and the udder, previously washed with soap and warm water, was sponged with ether, after which the teats were again carefully wiped with sterile cotton wadding wrung out in the lysol solution. A stream of milk was then withdrawn by hand (the hands having been carefully washed and disinfected) before a sterilised milk tube was passed up the teat into the milk sinus. The milk tube connected by a piece of rubber tube to a sterilised flask (the whole having been previously sterilised as one piece) allows the milk to pass readily into the flask, which was taken to the laboratory at once and a series of plates made. Various colonies of streptococci grew as a rule, although in some cases the plates did remain sterile. It seems probable, therefore, that, in a cow which has suffered from mastitis. the infecting organisms remain in the milk ducts and sinus, live a saprophytic existence. and induce by chemiotactic influence the presence of the polymorphonuclear cells.

Pathological Conditions Affecting Milk-supply.

External Injury.—The cellular content of the milk of any quarter of an udder which has received some external injury may or may not be altered.

Abscess Formation.—A case of a slight superficial abscess came under my notice, which was opened and gradually healed, but during the time the case was under observation there was no alteration in the cellular content of the milk. If an abscess be deep and has infiltrated the gland, its presence is at once shown by the increased number of phagocytic cells: if acute, the phagocytic activity of the numerous cells is marked, if chronic and beginning to be shut off by fibrous tissue, the polymorphonuclear cells are less numerous, and less sharply defined. The other cells do not appear to be increased in numbers under these circumstances.

Experimental Inflammation.—This was done on a goat, an injection of an emulsion of streptococci being made into the L.Q. The milk from both quarters was carefully examined the day after injection. when it was found that the films from the milk of the R.Q.

remained the same as before the experiment, while those of the infected L.Q. were crowded with polymorphonuclear leucocytes. Many were actively phagocytic and had engulfed the streptococci, but many were in various stages of disintegration. It is interesting to note that the R.Q. presented no signs of any inflammation, and yielded the same quantity of milk with the same cellular content; whilst on the third day the infected quarter almost ceased to yield any. The observations were discontinued after the sixth day, when the infected quarter still gave an abnormal cell count, although from its clinical appearance one would have said that it had returned to normal.

Phagocytosis.—That the polymorphonuclear cells described above were actively amœboid and phagocytic was demonstrated in the following way. Within half an hour of milking a drop of milk was placed in a small glass chamber made by placing a ring of plasticine on a glass slide and covering it with another slide. The chamber, full of fluid, was incubated for ten minutes. The slides were then pulled apart, the plasticine ring removed, and warm normal salt solution poured gently over the slides to wash off the milk and the excess of cream; the slides were then allowed to dry and were stained by Jenner's method. The film which adheres to the upper slide is composed of wandering cells which have by their active movements made their way to the top of the chamber, while the tissue cells, together with inactive wandering cells, were found in the film on the bottom slide. The film on the top slide was composed of polymorphonuclear cells entirely, many of them actively phagocytic, while the bottom slide was covered with a film of blue cells, consisting of lymphocytes and epithelial cells with a few polymorphonuclear cells badly stained. The milk from the normal quarter treated in the same way left the upper slide entirely devoid of cells, but adhering to the bottom slide, however, were cells of all varieties. This differential arrangement seems to be a striking proof that the polymorphonuclear cells found on the upper slide are none other than the actively amœboid phagocytic cells of the blood, these being probably called out into the milk spaces by an irritant which has tended to set up an inflammation.

The cells then found in the sediment are almost all of one variety, large blue oval or round cells with granular protoplasm, and with a large delicately stained nucleus. They are not phagocytic nor amœboid, and when the modified Ponder's method is employed are found adhering to the bottom slide of the chamber. The whole subject of milk production is here involved, and it is highly probable that experiments carried out along the lines described above may give the key to the solution of a very vexed question. At all events the above experiment seems to indicate that one of the constituents of the cellular content of milk is derived from the tissue cells of the acinus, and that under special stimulation the numbers of this cell are increased, the special blood cells persisting in their original and normal proportion.

Source of Cells Found in Milk.—It is held very generally that all the cells found in milk are purely blood cells, but Winkler[5] and his school maintain that they are entirely of epithelial origin. On the one hand we have such statements as the following: "The outstanding feature in the examination of some hundred films prepared both from normal cows at different periods of lactation and from cows presenting slight signs of mastitis and representing many thousands of cells, is that *no cell having any decided resemblance to a polymorphonuclear leucocyte has been detected*, and phagocytosis of bacteria present is conspicuous by its absence." (Hewlett, Villar, and Revis.[6]) It is obviously difficult to concur in this view, the polymorphonuclear cells described in this paper being identical with those found in the blood.

These leucocytes must be regarded as pus cells when in the course of time they break down and disintegrate. The slightest inflammation of the udder is followed by the appearance of a considerable number of these cells whose characters are always the same, and whose phagocytic activity, when examined fresh, can be demonstrated. Many of my drawings show this very clearly, and I cannot agree with those observers who say that phagocytosis "is conspicuous by its absence." I am, however, in agreement with those who point out that the cell with a single oval or rounded nucleus, which stains well but not always uniformly, the cytoplasm of which is structureless and which stains well with eosin, is derived from the secretory layer of the gland tissue. This cell, which I regard as epithelial in type, is present in large numbers when the gland tissue ceases to perform its proper function as the cow "dries off." On account of its sometimes having a double nucleus it is apt to be mistaken for a polymorphonuclear cell, and by many authors it is regarded as a pus cell. The small blue cells described above as lymphocytes are really the lymphocytes of the blood-stream. Again, the coarsely granular eosinophile cells and the basophile cells which are so often present in milk undoubtedly correspond to similar cells found in the blood.

The other cells are epithelial in type, while a few are undoubtedly derived from lymphoid tissues.

Presence of the Red Blood Corpuscle in Milk.—It would not be accurate to say that *every* sample of milk contains red blood cells, but it is *undoubtedly true* that 99 per cent. of the milk samples which I have examined have contained erythrocytes. Even in normal milk—using the term in its strictest sense—I have met with an occasional red blood corpuscle. In acute congestion of the udder red corpuscles make their appearance, and they are always present also in the first milk or colostrum after calving.

Causes of the Presence of Blood in Milk.—The commonest cause of the presence of blood in milk is said to be rupture of a blood-vessel. This may be true where large numbers of erythrocytes are met with, but it is certainly not the case where the blood is detected only on microscopic examination of the milk. Apart from pathological and mechanical sources of blood it is not generally recognised with what ease the red blood corpuscle can get into the milk-stream, and the fact that this can occur is undoubtedly a factor to be taken into consideration when one considers the possibility of pathogenic organisms—e.g., the tubercle bacilli getting into the milk-stream by the same route.

So far as these observations go it is evident that the cells in milk are partly blood cells, partly lymphoid, and partly epithelial. While it is impossible to agree with the statement that "no cell having any decided resemblance to a polymorphonuclear leucocyte" is present in milk, it is obvious that to concede that all the cells in milk are pus cells is equally out of the question. Although it must be admitted that at certain times, and under certain conditions, pus cells are found in milk, it does not by any means follow that, whenever the cell count is high, we are dealing with a purulent condition.

I have endeavoured to point out that although reliance cannot be placed upon a quantitative leucocyte standard, yet, by means of the differential count, it is possible to distinguish all the various conditions most accurately, and in many cases even to make a diagnosis, and to set up a qualitative standard which may be of great service. It is, indeed, necessary not only to modify the existing standards, but to revise our whole method of diagnosis. The method described in this paper, together with the results of the investigation, indicates a method of procedure which certainly promises to give more satisfactory results as regards diagnosis than have yet been obtained.

Summary.

It is possible by means of a differential stain to distinguish very accurately the various kinds of cells found in milk. Without this it is impossible to place any reliance on so-called cell counts, as an indication of a diseased condition of the udder.

By studying the relative number and types of cells in a milk film, it is possible to make an accurate diagnosis of the condition of the quarter of the udder from which the milk is obtained, and also to ascertain whether at any previous time that quarter has been involved in inflammatory trouble.

It is also possible to detect the process of "drying off" in cows. The cells appearing in the milk during that phase being tissue cells, are easily distinguishable from the inflammatory cells—the polymorphonuclear variety.

The different cells found in milk are classified and described.

It has been pointed out that the quantitative cellular examination of milk fails because it is impossible to detect small numbers of cells when the milk is greatly diluted; nevertheless, the differential count will often draw attention to some special feature and indicate the desirability of further investigation. The differential count reaches its highest value when used for the examination of milk from individual cows, and especially of the separate quarters of the udders of such cows.

Again, much valuable information can be obtained by examining the milk from each quarter, as fore milk, middle milk, and "strippings." Usually the strippings contain the greatest number of cells, but there are notable exceptions to this rule. The amount of deposit from these samples does not always give an indication of the number of cells present.

The various factors influencing the cellular content of milk have been considered under the following heads:—

Physiological.

1. The breed of cow seems to be an important factor, for by careful examination it is possible to determine from amongst normal animals of several breeds the source of the milk sample.

2. The effect of time after calving, together with the changes in composition of the milk from colostrum to normal fluid have been noted and discussed.

3. The intervals between milking, together with the time of milking, have been shown to be factors of considerable importance in determining the cellular content of milk.

4. The question of the relation of the cream content to the cellular content shows that there is a very constant relationship between the two; with an increase of certain cells the cream may also increase, whilst with the increase of other types of cells it is decreased. An increase of inflammatory cells is invariably associated with a low cream content, but it by no means follows that the converse is true.

5. The drying off process is associated with a definitely increased output of cells, essentially different from the polymorphonuclear variety. They are tissue cells, and are not associated—as some authors maintain—with an outpouring of pus in this condition.

Pathological.

We have seen that the cellular content of milk is profoundly altered under pathological conditions. Of these: (1) some previous illness—e.g., milk fever, mastitis; (2) abscess formation involving the gland tissue; (3) streptococcic infection, whether naturally acquired or by experimental injection.

The different cells which predominate under these varying conditions have all been referred to.

Mechanical.

Lastly, the mechanical factors which influence the cellular content of milk have been reviewed and discussed.

In conclusion, it is frequently stated that milk containing pus cells is unfit for human consumption. It is therefore of the utmost importance that we should be able to determine the presence of pus in milk. If it is true that it is impossible to distinguish between a pus cell and a leucocyte, it is obviously of no use to use a numerical method of counting all the cells in a given sample of milk. The only method of distinguishing a pus cell from a normal leucocyte is by means of a differential stain and a differential count, when their presence may be readily enough detected.

A CASE OF LEPROSY.

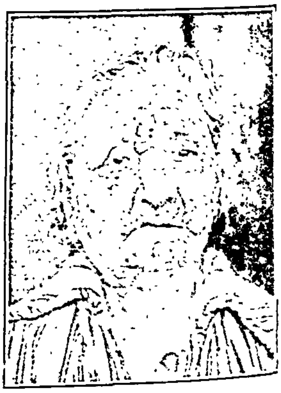
TREATED BY A VACCINE PREPARED FROM A NODULE FROM THE PATIENT'S ARM.

BY SIR NORMAN WALKER, M.D. EDIN.

With a Note on the Preparation of the Leprosy Vaccine by
Lieut.-Colonel GLEN LISTON, C.I.E., I.M.S. (Ret.),
and a Note on the Histology of the Case by
J. W. DAWSON, M.D., F.R.C.P.

(*With Coloured Plate.*)

MRS. F——, a Russian Jewess, aged 70, came to Scotland from Kovno over 40 years ago and has lived here ever since. She has been married for 52 years and has had two children, both of whom are alive and well. She states that up to four years ago she was in perfect health and had no eruption on the skin. I have questioned and cross-questioned her; I have had the assistance of the Rabbi, and her statement remains unshaken. I have tried to ascertain whether she had had living with her for any length of time compatriots from regions where leprosy is endemic, but no evidence of this is forthcoming. She came to the Royal Infirmary, Edinburgh, in January, 1923, when she presented the appearance shown in the photograph (see figure). The appearances on the face are, of course, characteristic of leprosy; the nodules were, so far as my experience goes, rather larger and redder than usual. It is, as all who have had to deal with this disease know, a common experience that a good deal of tact is required in the admission of such patients to a hospital ward, and it was some time before I thought the conditions were suitable.



She was admitted to my ward on August 24th, 1923. Nodules were excised at different stages for microscopic examination, and the findings are described later by Dr. J. W. Dawson, histologist to the laboratory of the Royal College of Physicians of Edinburgh. A few days after her admission she was put on injections of chaulmoograte of sodium, and these were continued for three or four weeks, an injection being given twice weekly. The pain, however,

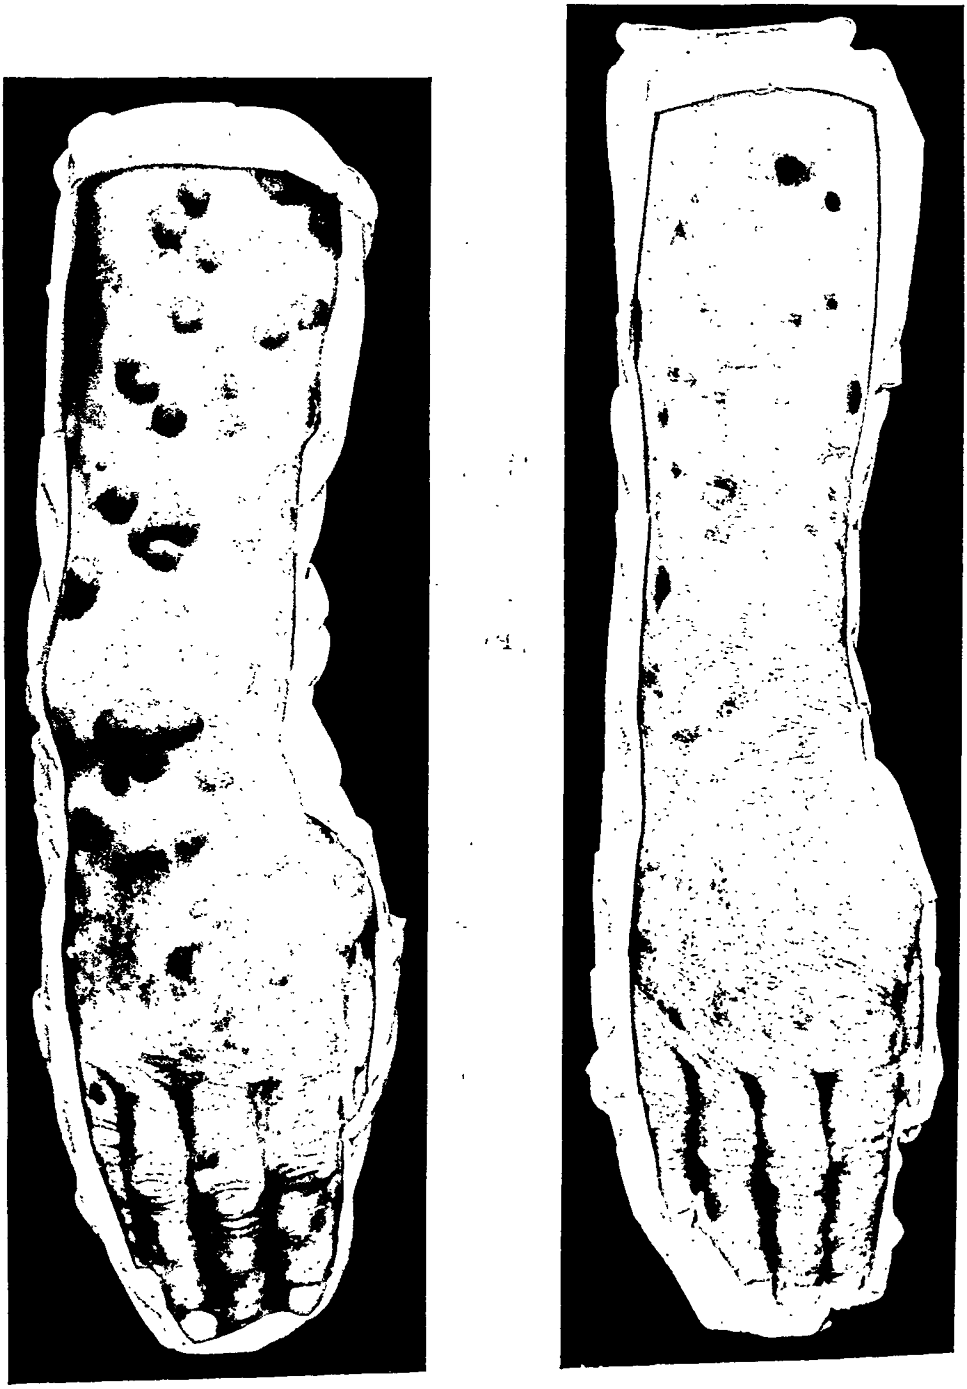
DR. P. C. VARRIER-JONES: THE CELLULAR CONTENT OF MILK.



SIR NORMAN WALKER: A CASE OF LEPROSY.

was very severe, and although she was in every way an admirable patient, her sufferings were evidently too great to warrant one in continuing the treatment.

For several years I have been treating most of my numerous cases of lupus with a vaccine prepared direct from tuberculous glands (either human or bovine) according to the method suggested by Dr. McGowan and Mr. John Fraser, with, I am convinced, very excellent results; and it occurred to me to try a similar method in this case. (See Col. Glen Liston's note below.) From October an injection was given weekly, and the first cast was taken on Oct. 4th. No pain was associated with the injection and the poor old lady's gratitude for this was quite touching. Within three weeks improvement was noticeable, and it proceeded with accelerated strides until the whole eruption had reached the stage shown in the second of the coloured casts, which was taken on April 22nd, 1924. The improvement is indeed so striking that it is not necessary to occupy space in describing it. Her general condition has improved, though at no time did she show any marked deterioration of health.

I have come across one or two references to the treatment of cases by vaccines made from the nodules, but in none are there details of such encouraging improvement as has occurred in this case. I hope others with larger opportunities will give the method a trial. Nearly 40 years is a long period of incubation, but I believe a period as long has been noted, and there does not seem to be any other explanation for the occurrence of the case. No bacilli were found in the nasal secretion.

NOTE ON THE PREPARATION OF THE LEPROSY VACCINE.

By Lieut.-Colonel W. Glen Liston,

BACTERIOLOGIST TO THE LABORATORY OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A nodule on the skin of the forearm having been selected, the skin was thoroughly cleansed with alcohol and ether. Ethyl chloride was used to produce local anæsthesia and the nodule, having been cut out with aseptic precautions, was placed in a sterile vessel and removed to the laboratory. Here the nodule was cut into small pieces and then ground up with sterile sand in a mortar, a little normal saline being added gradually till a thick emulsion was produced. The emulsion was decanted into a sterile test-tube and allowed to stand till the heavier particles had settled. The supernatant cloudy fluid was decanted off into another tube and then examined microscopically.

It was found to consist, for the most part, of leprosy bacilli with a small quantity of cellular debris. The majority of the bacilli were present in clumps of two or more elements, so that attempts to count the number of bacilli present in the emulsion gave rather irregular results. The emulsion thus prepared was heated for half an hour at 60° C., and when diluted with carbol saline constituted the vaccine. The vaccine was put up in 1 c.cm. capsules of such a strength that approximately 200 million leprosy bacilli were present in each c.cm. The first dose recommended was 0·1 c.cm., which could be increased as indicated by the condition of the patient. She is now receiving 1 c.cm. weekly.

NOTE ON THE HISTOLOGY OF THE CASE.

By J. W. Dawson,

HISTOLOGIST TO THE LABORATORY OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

The sections of the earlier nodule show the presence of a very cellular granulation tissue occupying the superficial layers of the corium, with a slight infiltration of the deeper layers, especially along the lines of the vessels. The cells are closely placed together and consist of (1) small, rounded or oval forms, with a comparatively large, deeply-staining nucleus; and (2) large mononucleated forms in large numbers—the so-called "lepra cells"; these are fusiform or rounded and have a vesicular nucleus and often a vacuolated protoplasm. A few large cell forms with several nuclei are present, but no cells similar to the giant cells of tubercle. The actual stroma is very delicate and there are numerous thin-walled capillaries, so that there is no necrosis and no caseation. In sections stained specially for the leprosy bacillus, the large "lepra cells" are found packed with rod forms in characteristic groups, while many bacilli are present free in the tissue spaces and a few in connective-tissue cells.

The sections of the later nodule, after treatment, show that the tissue is more fibrous and much less cellular. Many of the larger cells are present, but are of a fibroblastic character. Under the low power there is a suggestion of an early focal necrosis of the cells, and the small-celled infiltration of the efferent perivascular lymphatics is less marked. In sections stained for the bacillus, a few typical "lepra cells" are still present containing rod forms, but the great majority of the large cells present contain only vacuoles or granules of varying size. The granules are present also free in the lymphatic spaces, and both within and without the cells may fuse to form small masses. As the staining reaction of the granules is similar to that of the rods, the appearances are strongly suggestive of the granular disintegration of the bacilli and are quite distinct from that of the eosinophile cell granules present.

Summary.—In the early nodule the structure is that of a cellular granulomatous tissue and the bacilli are present entirely in rod form within the "lepra cells" and free in the tissue spaces. In the later nodule there is (1) a building up of a granulation scar tissue; (2) a breaking up of the bacillary rods into granules (the "globi" of Hansen) and their gradual disappearance.

THE ACTION OF QUINIDINE IN THE TREATMENT OF HEART DISEASE.

BASED ON THE EXPERIENCES OF CERTAIN MEMBERS OF THE CARDIAC CLUB.

By JOHN HAY, M.D. Manch., F.R.C.P. Lond.,
SENIOR HONORARY PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL;
PROFESSOR OF MEDICINE, LIVERPOOL UNIVERSITY.

At a meeting of the Cardiac Club in Edinburgh in 1923 there was a discussion on the value of quinidine in fibrillation of the auricles, and the members gave their varied experiences. It was suggested that it would be of some interest and value if this experience could be pooled. A questionnaire was accordingly drawn up and sent to each member, requesting information concerning the method of administration, the type of case, the nature of response, and the occurrence of any toxic effects or misadventures during the exhibition of the drug,* and the results were presented in the form of a report to the next meeting of the Club at Bristol in June, 1924.

As the administration of quinidine has become a not uncommon method of treatment in fibrillation it was thought that the publication of the results might be of service.

On attempting to analyse the figures received it was clear that only simple grouping was possible if the results were to be pooled. The cases have accordingly been arranged under three headings:—

(1) One hundred and sixty-six patients suffering from auricular fibrillation and V.D.H. (2) Eighty-seven patients suffering from auricular fibrillation but no V.D.H. This group included patients with arterio-sclerosis and myocardial degeneration, high blood pressure, syphilitic disease, and others in whom the condition of the heart muscle was not stated. The presence of mitral incompetence was not considered in itself as justifying a diagnosis of V.D.H., and such patients were included in this group. (3) Twelve thyrotoxic cases and those with Graves's disease; giving a total of 265 patients.

---

* The following are the members from whom replies were received: J. C. Bramwell, T. F. Cotton, C. F. Coombs, John Cowan, J. G. Emanuel, F. R. Fraser, John Hay, C. E. K. Herapath, J. E. MacIlwaine, J. Parkinson, W. T. Ritchie, J. Starling, and K. D. Wilkinson.

Method of Administration.

This has varied considerably, and may account for the striking difference in the quality of the results obtained.

The schedules show clearly that in most successful cases the total amount of quinidine required to obtain a sinus rhythm is not large. From 1 to 3 g. is frequently sufficient, although sometimes massive doses continued over some days may succeed when the more usual dosage has failed.

The following may be taken as samples of the methods employed:

1. F. 5 gr. ter in die, increasing to 7 gr., and later to 10 gr. ter in die.

In cases that did not respond well to digitalis and in other ways were not quite straightforward, a trial dose of 2½ gr. or 5 gr. was given.

2. R. First day, 0·2 g. twice daily; second day, 0·2 g. thrice daily: third day, 0·4 g. thrice daily; fourth day, 0·4 g. thrice daily; and so on until the tenth day, when the drug is stopped if fibrillation persists.

3. C. C. 5 gr. (0·3 g.), five doses in 24 hours = 25 gr. in four days.

Digitalis is given first to slow down the heart, and is sometimes given concurrently with the quinidine.

4. B. Initial dose, 0·2 g.; 24 hours interval, followed by 0·4 g. t.i.d., increasing, if necessary, until received 0·4 g. six times a day = 2·4 g.

5. H. After initial tentative dose of 0·2 g., 2 g. is given in 24 hours in ten doses of 0·2 g., conveniently spaced. This may be increased to 3 g. per day, by doubling the amount of the quinidine in five of the ten doses given in the 24 hours.

Before the administration of the quinidine, digitalis is given if there is rapid action of the ventricles or signs of decompensation.

Treatment after the Resumption of Sinus Rhythm.

In this there is no uniformity. By some the dose of quinidine is gradually reduced and a history of palpitation or irregularity is considered as an indication to keep up the dosage for a longer period; or 0·2 g. are given twice daily for the first week, and 0·2 g. once daily for the next fortnight. Others have continued with the full dosage of quinidine whenever there is a liability to relapse, but even massive doses have failed to prevent the recurrence of fibrillation in some patients.

The general opinion is in favour of giving quinidine for some time after the restoration of a normal rhythm.

Consideration of Results of Treatment.

In each group the result is given under one of three headings:—

Failure.—Complete, in which the fibrillation persisted in spite of treatment.

Success.—Temporary. The quinidine succeeded in breaking the fibrillation, but after a few hours or weeks the auricles reverted.

Success.—Permanent. Where the normal rhythm had remained up to the date on which the schedule was sent off, or where the period of normal rhythm was of months duration.

It is hardly necessary to point out the difficulty in stating the number of permanent successes, or to give the figures truly representing the proportion of those who maintained a normal rhythm to those who reverted, because there is a constant tendency in these patients to revert to fibrillation.

Group 1.—Auricular fibrillation with V.D.H., 166 cases. Failure complete in 78; success temporary in 42, equals 120 ultimate failures; success permanent in 46. In this group of 166 cases the fibrillation was broken in 88 patients, or 53 per cent. In 42 patients the success was only temporary, which gives 120 ultimate failures and 46 successes.

Group 2.—Auricular fibrillation in hearts free from V.D.H., 87 cases. Failure complete in 28; success temporary in 24, equals 52 ultimate failures; success permanent in 35. This includes a variety of types of heart on which the fibrillation had been grafted, but the results are definitely better than in group 1. The fibrillation was broken in 59 patients, or 64 per cent.

In group 1 the percentage of permanent successes is only 27·7 per cent.; in group 2 the percentage of permanent successes is 40·2 per cent.

However, it is obvious that stress cannot be laid on these percentages, because there is no certainty about the persistence of the normal rhythm, and unfortunately sooner or later reversion is likely to recur in an indeterminate number of the patients.

In group 2 were included five patients in whom there was evidence of *markedly increased blood pressure.* In two of these the normal rhythm was maintained, in two the heart reverted to auricular fibrillation, and in one patient the normal rhythm was never attained.

There must be other instances of raised blood pressure, but they were not indicated in the schedules.

Group 3.—Including the thyrotoxic cases and Graves's disease. The number of cases reported is small, but the results are good. Cases in all, 12. Failure complete in 3; success temporary in 1, equals 4 ultimate failures; success permanent in 8.

The following are the combined figures for the 265 cases:—

Failure complete, 109; success temporary, 67, equals 176 ultimate failures; success permanent in 89.

Quinidine did, however, restore a normal rhythm in 156 of these patients, or in 59 per cent.; though in 67 the fibrillation returned.

Toxic Manifestations and Misadventures.

The administration of quinidine is not entirely devoid of danger, and not infrequently causes distressing symptoms. The reports received dealing with the toxic effects of quinidine and the possible misadventures associated with its exhibition are therefore particularly valuable, and cover 286 patients.

Certain minor results were not infrequent, such as headache, nausea, vomiting, diarrhœa, abdominal pain, giddiness, faintness, buzzing in the ears, general distress, a sense of apprehension, palpitation, precordial pain, excessive ventricular rate, orthopnœa, sweating, toxic erythema, and urticaria.

Idiosyncrasy may be marked, and it is then impossible to push the drug—a tentative dose will discover this disability. It is rare, however, to meet with a sensitiveness so marked that treatment cannot be attempted. Slight unpleasant manifestations of discomfort should not be allowed to prevent a reasonable trial.

These manifestations and misadventures are given fully. This portion of the report deals with all patients to whom quinidine was administered, and includes those suffering from paroxysmal tachycardia and auricular flutter, in addition to the cases of auricular fibrillation.

Of the 286 patients dealt with in this section of the report eight died suddenly, and embolus occurred in seven. One of the deaths in this series (1) was apparently not in any way due to quinidine.

1. One patient died about 36 hours after a single dose of 0·3 g., probably because of violent mania (death due to psychical causes and not to quinidine).

2. Death sudden and unexplained. Embolism had not occurred.

3. Quinidine stopped after two days because of fainting attacks. Died two days later, suddenly, possibly ventricular standstill. Female, 60. Exophthalmic goitre. No V.D.H. Thyroidectomy.

4. Sudden death by failure of breathing after two doses of 0·2 g. Female, 30. Mitral stenosis.

5. Normal rhythm after 75 gr. of quinidine without any trouble. Reverted in three days. On the fifth morning of the second course of quinidine his physician entered the ward and found him asleep; while he stood by feeling the pulse the patient woke up, said he felt remarkably well that morning, and died. Male, 55. No V.D.H.

6. History of numerous attacks of fibrillation. During attacks patient felt ill, but was unaware of the rapid and irregular action. Rate of heart 180 or more. Radial pulse not palpable. Full doses of digitalis had no effect and as the attack has lasted over ten days, quinidine was given. She had about 60 gr. and died suddenly. Female, 31. Paroxysmal tachycardia.

7. Patient suffering from paroxysmal tachycardia. Quinidine was administered; 2 g. were followed by cessation of the paroxysm and everything was progressing satisfactorily, when suddenly, without warning, she died. No autopsy.

8. Sudden death. Ventricular fibrillation. Autopsy: no cause of death found. Male, 27. Rheumatic, mitral disease. With great enlargement of the heart.

The following are the details in the seven cases of embolism:—

1. Cerebral embolism—right hemiplegia. Onset eight days after restoration of normal rhythm. Recovery.

2. Pulmonary embolism. Three hours after restoration of normal rhythm. Recovery.

3. Cerebral embolism. Normal rhythm after 34 g. No material change in the subjective symptoms. Four days later, left hemiplegia, hemianæsthesia, conjugate deviation to the right; no loss of consciousness, no pyrexia. Normal rhythm maintained. Male, 37. Double mitral lesion of old standing.

4. Cerebral embolism. Rhythm normal after 0·6 g. Sixteen hours later right hemiplegia and aphasia. Reversion to fibrillation 28 hours later. Female, 45. No V.D.H. High blood pressure, large heart, and persistent tachycardia. No response to digitalis.

5. Embolism of right popliteal artery and gangrene of two toes occurred within 24 hours of reversion to normal rhythm. There was also a small patch of gangrene of the right ear. Male, 52. Flutter. Normal rhythm maintained for at least 12 months.

6. Embolism in the leg within six hours of reversion to sinus rhythm. No gangrene. Male, 29. *Fibrillation.*

7. Embolism in left brachial artery within 12 hours of resumption of normal rhythm. Female, 39. Early mitral stenosis. Fibrillation.

Symptoms of ventricular stoppage were noted twice:—

1. Adams Stokes attack. Ventricular standstill. Female, aged 31. Mitral stenosis. Ventricular rate 50–60. Recovered and reverted.

2. Adams Stokes syndrome after 1·4 g. Male, 34. Mitral stenosis.

Hallucinations of light with left-sided hemiplegia, lasting a few hours, occurred in a female of 52, suffering from mitral stenosis. The sinus rhythm was only temporary. This case might fairly be included in the series of embolisms.

In another patient, a female of 44, suffering from mitral stenosis, quinidine induced epileptiform attacks with cyanosis of the face, stertorous breathing, and twitching of the hands and face. The sinus rhythm was not maintained.

Such being the probability of obtaining a normal rhythm, and such the distress and liability to accident associated with the administration of quinidine, the question naturally arises: How far are patients benefited by the resumption of a normal rhythm, and in what particular type of case should quinidine be exhibited? In other words, when is it worth while?

Cases Unsuitable for Quinidine.

There are certain patients to whom it is admittedly unwise to administer quinidine.

1. It is more than probable that little or nothing is to be gained from quinidine in badly damaged hearts with old-standing valvular disease, and more particularly if there is undoubted failure of compensation with venous engorgement.

Here digitalis *is the best* drug to administer in the attempt to control the ventricular rate and improve the reserve power of the heart.

2. Occasionally, *in a patient* who has suffered severely from angina pectoris, the onset of fibrillation is followed by the cessation of the anginal pain, and it is a question whether one should attempt to restore a normal rhythm under these conditions.

3. Idiosyncrasy. Rarely the patient is unduly sensitive to quinidine, and to push the drug induces unpleasant or even dangerous consequences.

4. All cases of acute or subacute infective endocarditis.

5. A history of embolism would be a factor against the administration of quinidine.

Cases Suitable for Quinidine.

Quinidine is most likely to be of service when the fibrillation is of recent development, and when there is but little cardiac enlargement and no valvular disease; as, for example, a case of paroxysmal fibrillation with the last paroxysm persisting.

Another favourable type of case is that of a patient in whom the onset of fibrillation was due to, or at any rate associated with, an acute infection, such as influenza or the presence of an infective focus.

A man, aged 50, who gave a history of frequent sore-throats, suffered from an acute febrile attack. Fibrillation occurred and an embolus lodged in the popliteal artery. Gangrene of two toes began. Enucleation of the tonsils was followed by cessation of fever. Quinidine, 4 gr. four-hourly, restored the normal rhthym after treatment for four days. The normal rhythm has been maintained for the past five months.

When the onset of distress definitely dates from the inception of fibrillation, and it is clear that the abnormal rhythm is the disabling factor, then the advisability of administering quinidine should be favourably considered.

Quinidine has proved of great value in the fibrillation associated with exophthalmic goitre, especially where partial thyroidectomy has been performed and the fibrillation persists. Quinidine is also valuable before operation in the milder cases of Graves's disease in which fibrillation is present.

It is clear that each case must be considered on its merits. There are no hard-and-fast rules. Often the results are far better and more permanent than was to be expected—more frequently, however, they are disappointing. Either the fibrillation persists or the recovery is only temporary.

When it is permanent most patients are conscious of some change for the better. The symptoms are ameliorated and the cardiac reserve is increased. In favourable cases a normal mode of life is resumed.

The Effect of Return to a Normal Rhythm.

Quinidine is given with the hope that it will restore a normal rhythm. Even when it is successful the result is sometimes disappointing—there may be no appreciable advantage gained, and, in fact, the patients are sometimes unaware of the change of rhythm; either because the discomfort induced by the fibrillation was so slight or, as in the case of the gravely ill, the cardiac distress, irrespective of the fibrillation, is so great that the additional disability is not appreciated. As a rule, however, the return to a sinus rhythm is accompanied by some measure of relief, the distressing palpitation is removed, and the consciousness of the irregularity disappears; and as these two symptoms are enough to cause insomnia, their disappearance is followed by restful nights and consequent benefit. Improvement is great in the thyrotoxic cases, and in them especial emphasis is placed on the relief resulting from the cessation of palpitation. With the return to a normal rhythm there is usually an increase in the cardiac reserve, sometimes, indeed, so material that work is resumed. The patient finds that he can mount stairs with greater ease and can walk farther and faster.

A male, aged 62, with a much enlarged heart but no valvular lesion, whose auricles had fibrillated for at least six years, had been unable to work during the whole of this period. He required very large doses of quinidine before the restoration of normal rhythm six months ago. Since then he has followed his occupation of traveller.

Another case was that of a female, aged 50. Fibrillation followed influenza and had persisted for six months. Œdema, extreme dyspnœa, and tachycardia were present. Since the return to normal rhythm eight months ago she has been back at work.

There is some difference of opinion concerning the degree of improvement resulting from the administration of quinidine, and from the various reports it is obvious that there is an increasing tendency to give quinidine only to carefully selected cases. There is, however, remarkable unanimity as to its value in patients suffering from exophthalmic goitre and auricular fibrillation, for these patients are especially conscious of and distressed by the rapid and irregular ventricular action, and are correspondingly relieved and benefited by the return to the normal rhythm.

In conclusion, may I thank those who have supplied me with the data from which I have completed the report: a report, presented in the hope that the combined experience on which it is based may prove of service to the profession in the use of quinidine.

NOTE ON THE DETERMINATION OF SOLUBLE "PROTEIN" IN GASTRIC FRACTIONS FROM CASES OF CARCINOMA.

By C. S. HICKS, M.Sc., M.B., Ch.B.

(From the Pathology Department, Medical School, Dunedin, New Zealand.)

It was originally shown by Wolff[1] [2] that if the contents of a stomach after an Ewald test-meal were withdrawn, filtered, and tested for protein by a special precipitation reagent,* the normal stomach did not give positive reactions in such high dilutions as fluids drawn from a stomach affected with carcinoma.

For the same reasons that the Ewald test-meal is not so valuable as the fractional method of Rehfuss,[3] so it appeared to us that Wolff's method might be better applied fractionally, and, unaware of Clarke and Rehfuss's paper,[4] we carried out some tests. Although this is only a brief account of incomplete work done during routine examinations, we feel that there are one or two points worth drawing attention to, while at the same time focusing interest on a practical method which, as Rolfe [5] points out, is, however, imperfect at present, an additional aid to diagnosis in cases where every aid should be of value.

For the proper carrying out of the test, the test-meal—that of Ryle [6] was used in this series—is given on an empty stomach in the morning. The meal consists of two tablespoonfuls of oatmeal and a quart of water boiled down to one pint and strained through muslin. A sample of resting fluid is withdrawn before administering the gruel.

The specimens are filtered, and the filtrate diluted in a series of Wassermann tubes by addition of water. Thus, the first specimen is diluted 1 : 40, the next is made by adding equal volumes of the first to an equal volume distilled water, repeating up to the required limit in each case.

It was found that the ordinary gastric test-meal so examined seldom gave positive reactions beyond a dilution of 1 : 40, and never beyond 1 : 60 towards the end of digestion. In cases of verified gastric carcinoma the results were sometimes quite remarkable, while in all cases positive results were obtained in much higher dilutions than normal. This has been pointed out by Clarke and Rehfuss,[4] the difference being that they made use of the Ewald meal of tea and toast, and apparently were able to get positive tests for protein from the same in dilutions of 1 : 320 towards the end of normal digestion. This introduced a factor which they eliminated by taking as positive pathological tests only those which showed a rapid rise in soluble protein out of proportion to digestive activity. Although, using the Ryle test-meal, this difficulty was not apparent, their reservation is a good one for conservative reasons.

Next, cases in which obvious blood had escaped into the stomach were examined with a view to discovering whether the positive tests were due to serum protein. The results were interesting. In no case of gastric ulcer, with hæmatemesis, could the high figures common in carcinoma be obtained, and further, the results, plotted as a graph, were not comparable. On examining the fractions from carcinoma cases, by precipitation with ammonium sulphate, it was found that Wolff's reaction still occurred in the filtrate, and it was concluded that the causal factor is something of the nature of proteose. Why positive tests in carcinomatous stomachs should be obtained with achylia and achlorhydria is difficult to explain, especially when an actively secreting stomach with serum effusion from an ulcer does not give such high results. It is suggested that the neoplastic tissue in breaking down undergoes autolysis and digestion more readily.

No.	Rate of emptying.	Resting fluid.		Maximum.		Maximum "soluble protein."	Final total acid.
		HCl.	Total acid.	HCl.	Total acid.		
1	1 hour	0	15	0	15	1 : 480	8
2	2½ hours	0	10	8	25	1 : 640	15
3	1 hour	0	10	0	12	1 : 640	5
4	2½ hours	0	10	0	30	1 : 1280	10
5	1¼ ,,	5	10	15	28	1 : 320	12
6	3 ,,	10	25	0	25	1 : 1280	23
7	3 ,,	2	16	8	15	1 : 280	13
8	4 ,,	0	40	0	13	1 : 640	11
9	3 ,,	5	28	4	22	1 : 320	10

The table shows data taken from fractional test-meal analyses in nine separate cases of carcinoma of the stomach. Time of emptying, as shown by rate of disappearance of food: acidity, both total and due to hydrochloric acid of the resting juice, and at the highest subsequent point reached during the test, together with the final total acid at three hours, are quoted. Maximum "soluble protein" figures represent dilutions giving positive tests at the end of the third hour—i.e., conclusions of test.

FIG. 1.

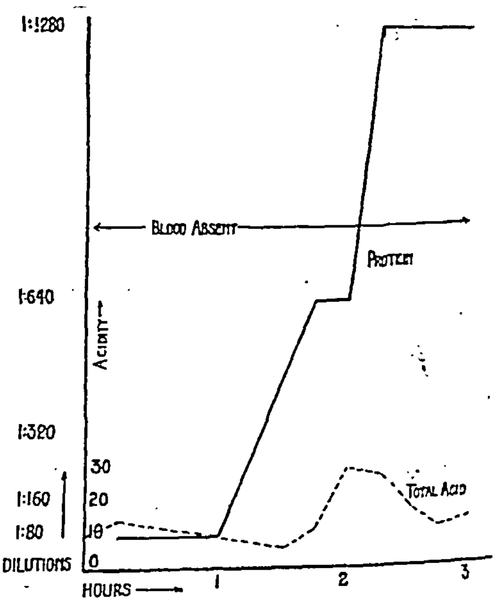


FIG. 2.

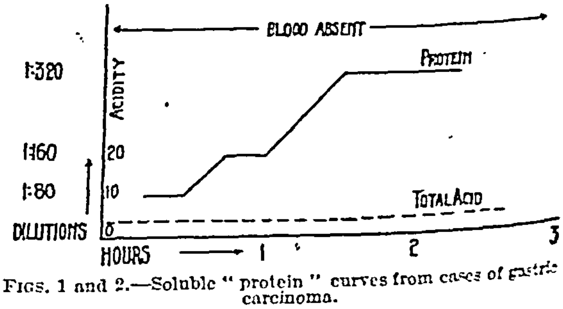

FIGS. 1 and 2.—Soluble "protein" curves from cases of gastric carcinoma.

Among the cases examined some did not come to operation for various reasons, and from those quoted which were verified either at operation or at autopsy there is not sufficient evidence to be drawn as to how the type of carcinoma affects the result. One case of fungating soft carcinoma of the pylorus gave results only up to 1 : 280—a figure reached in 90 minutes. The case came to autopsy (No. 7).

---

* Phosphotungstic acid reagent: Phosphotungstic acid, 0·3 g.; alcohol, 95 per cent., 20·0 c.cm.; concentrated hydrochloric acid, 1·0 c.cm.; distilled water to make 200 c.cm. Layer the reagent with great care, on the surface of the suspected fluid, by means of a fine-bore teat pipette. Examine against a dark background.

The graph Fig. 1 represents the result of a case of inoperable carcinoma involving the lesser curvature (No. 4), and Fig. 2, that from carcinoma of the body of the stomach with much glandular involvement.

Examples of gastric ulcer with much blood effusion are given as comparisons. In both the tubes were black with "coffee grounds," and hæmatemesis had been a marked symptom. One case shows an achylia and achlorhydria, the other an almost normal acid curve (free acid not represented diagrammatically), Figs. 3 and 4, in benign achylias, and those associated with pernicious anæmia tests for soluble protein, could not be obtained in dilutions greater than 1 : 40, in all seven cases being examined.

FIG. 3.

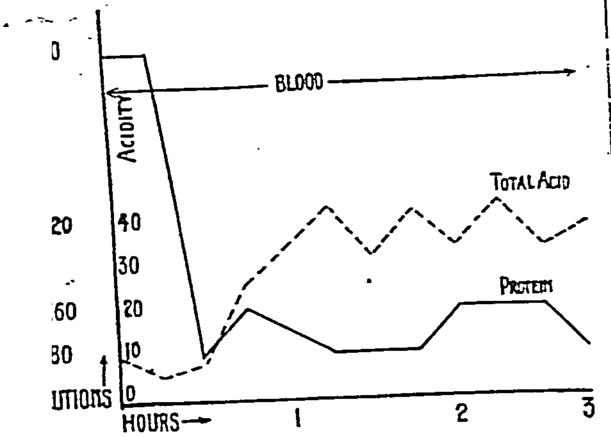

FIG. 4.

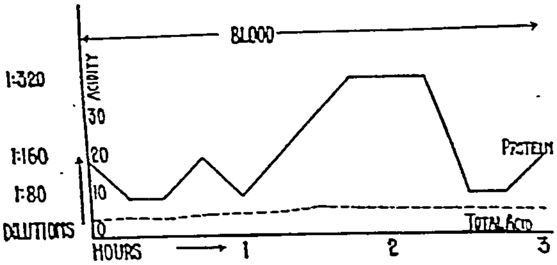

FIGS. 3 and 4.—Soluble "protein" curves from gastric ulcer cases.

In conclusion, Clarke and Rehfuss's[4] recommendation that before basing conclusions on the test all sources of protein from previous meal, from blood, and swallowed pus, &c., should be carefully excluded is a sound one, but blood effusions certainly do not give the same type of result as is obtained with carcinoma.

As it is difficult to express these results other than graphically, which method required space, it can only be stated that the gastric ulcer cases illustrated represent two of 11 separate cases studied.

Summary.

1. Serum effusion is not the factor involved in the Wolff Junghaus test for protein in gastric fractions.

2. The fractional application of the test gives results which help to distinguish a benign from a malignant achylia, and which merit closer attention in practice.

SOME NOTES UPON BLOOD TRANSFUSION IN EGYPT.

BY ROBERT V. DOLBEY, M.S. LOND., F.R.C.S. ENG.,
DIRECTOR OF THE SURGICAL UNIT: SURGEON TO THE KASR-EL-AINY HOSPITAL, CAIRO;

AND

A. W. MOORO, F.R.C.S. ENG.,
SURGICAL REGISTRAR AND TUTOR TO THE HOSPITAL.

BLOOD transfusion has been performed by us on 42 occasions in the last four years in Egypt; in 30 instances the whole blood method has been adopted; in 12 the citrated method. The conditions for which it has been employed are as follows:—

1. *Primary hæmorrhage:* as a treatment following loss of blood due to severe accidents or operations, and as a preparatory treatment in cases of severe accidents necessitating such operations as double synchronous amputations above the knees or elbows.

2. *Secondary anæmias:* as a preparatory treatment for operations upon individuals suffering from a low hæmoglobin value of the blood, particularly the secondary anæmias of ankylostomiasis and bilharziasis, where extensive operations for some organic surgical conditions are necessitated. In this respect it is our experience in Egypt as elsewhere that extensive operations performed upon individuals with 45 per cent. hæmoglobin or less are almost uniformly followed by fatal results.

3. As a stimulus to *blood formation* in such cases as the grave secondary anæmias of ankylostomiasis and bilharziasis where, although the conditions themselves are cured, the anæmia persists. It appears that the blood-forming tissues have so long ceased to function that, even when the cause is removed, the effect persists. In such extreme cases as these, showing a 10 per cent. or 20 per cent. hæmoglobin, this anæmia continues until blood transfusion is undertaken. An immediate effect of raising the hæmoglobin to 60 per cent. or 70 per cent. is observed, followed in 10–20 days by a fall, and finally succeeded, after a month or two, by a rise to 85 per cent., which appears to be the normal for Egypt as compared with Europe. Our experience suggests that in whole blood there exist certain ferments or vital substances that stimulate the blood-forming tissues to the resumption of their function. In this respect we are in complete accord with E. L. Hunt and Helen Ingleby.[1]

4. In the treatment of *deficiency diseases*, such as diabetes, pellagra, and rickets, in order to supply vital substances which may temporarily or permanently stimulate the tissues at fault to resume their function. In pellagra we believe that blood transfusion is a most valuable remedy. Following the conclusions of Wilson[2] that pellagra is due to protein deficiency, and that the accompanying gastro-enteritis prevents the digestion of proteid food, we are of opinion that this is one of the possible means of supplying the deficiency. Whole-blood transfusion has been carried out in two cases of diabetes mellitus in young men; in one case with no effect upon the sugar tolerance, in the other followed by a normal sugar tolerance for 27 days, followed by a relapse to his original condition of hyperglycæmia. This and other results suggest that such vital substances as are transfused maintain a functioning existence or produce a temporary stimulus for about 20 to 30 days.

In the cases of men who give their blood we do not find that the loss of a pint produces any debilitating effect. The loss of a litre from a healthy individual on one occasion did not prevent him walking to his home after a short interval. During the war it was the experience of one of us (R. V. D.) that as much as 1 pint of blood could be removed on three different occasions from one particularly good donor in 48 hours with no ill-effect other than a slight rise in pulse-rate. The urgency for this course was extreme, and he was kept in bed for a week subsequently.

[2] W. H. Wilson: The Diet Factor in Pellagra.

Blood Grouping in Relation to Grafting and to Blood Transfusion.

We find in Egypt that we can verify the observations already made elsewhere[3] as to the efficacy of blood grouping in skin and bone and organ grafting as well as the transfusion of blood. In cases where, for various reasons, autogenous skin and bone grafts are impossible, we find that skin and bone of Group IV. donors are successfully incorporated by their new hosts, whereas the transfer of tissue in the presence of cross-grouping has failed.

Dr. A. T. Shousha, of the serological department of the Government of Egypt, has grouped 417 Egyptian bloods. It is his experience that the proportion of Group IV. donors is low as compared with Europe. Of those potential donors that have been tested about 24 per cent. are Group IV., 14 per cent. Group I., 30 per cent. Group III., and 32 per cent. Group II. In this respect his figures agree with the results obtained by Hirschfeld in his study of the serological differences between the bloods of different races.[4] [5] The biochemical race index of Egyptian blood is 1·07.

Blood Incompatibility in Relation to Race.

But we also find that there is no essential incompatibility in the blood of the various races in Egypt. The great majority of the rural inhabitants in Egypt are Egyptians, a race with very definite and fixed anthropological characters, brown skins and flat black hair. The type is as characteristic to-day as it was in Dynastic Egypt 2000 years B.C. The civilisations imposed from abroad upon Egypt in all the ages have largely vanished, but the fellaheen persist unchanged. There are three other racial elements most commonly met with in the cosmopolitan towns: the Negro, with woolly hair and coal-black skin; the Berberine or Negro-Arab, with less pigment in his skin and less kink in his hair; and the Levantine. The origin of the latter is uncertain, but he usually contains a mixture of Southern French, or Italian, Greek, Syrian, Turk, and Armenian grafted upon a Negro or Negro-Arab stock. We have successfully transfused blood in all these varying individuals and, on one occasion, we have successfully transplanted a bone graft from a Negro-Arab Berberine into the ununited ends of a fractured tibia of a fair-haired and grey-eyed Turco-Armenian.

There have been five instances of extreme and grave urgency where blood has been taken from untested donors and transfused. This condition is always liable to happen when the supply of tested donors fails in an emergency. In these cases it is our custom to give a small testing dose of blood as a preliminary and then to proceed after a few minutes to complete the transfusion. It was the experience of one of us (R. V. D.) in the war that, in similar circumstances of urgent need for transfusion, the
blo ungrouped grey-eyed and fair-haired Austrian
pr om Transylvania agreed most excellently

e more we have
ion in ion time

of blood after citrated blood transfusion nor any increased tendency to ooze in the case of lacerated wounds. In the war one of us transfused three patients suffering from gas-gangrene with the blood of recovered gas-gangrene patients, but with no marked results. We have had no experience with the transfusion of immunised blood in septicæmia as suggested by Almroth Wright.[6]

Effects of Transfusion of Incompatible Blood.

We have had no grave results from the incompatibility of bloods. There has been a certain train of definite symptoms which we attribute to incompatibility. The first is an irritable cough, of the same nature as we get so often in the bilharziasis out-patient department where ambulatory cases of this disease are treated by intravenous injections of tartar emetic. The next symptom which we attribute to incompatibility of blood is præcordial pain and distress. A high temperature with or without a rigor, after transfusion, is looked upon by us as evidence of incompatibility. It is perhaps due to the fact that our procedure is to stop the transfusion upon the *supervention of these symptoms* that we have had no fatal results. But we do find upon subsequent examination that in these incompatible cases the transfused blood has no good effect, and that blood pigment appears in the urine. It is probable that the gravity of the danger of incompatibility has been exaggerated; and we are of opinion that, *in any case, there is no value in incompatible blood*, especially as an oxygen carrier.

The two possibly communicable diseases for which we examine are syphilis and malaria. In this respect our attention has been drawn to a number of Egyptians who, without any clinical evidence whatsoever of syphilis, yet give a "doubtful positive" Wassermann reaction. Making all allowances for the personal factor in the bacteriologist who decides these tests, it is yet our belief that the universal parasitic diseases of Egypt, ankylostomiasis and bilharziasis, alone may be responsible for a modified positive Wassermann reaction. This point, however, is now under investigation. We have been unable to associate ourselves with the view that blood transfusion is of value only in cases of hæmorrhage. We have found that it is equally valuable in cases of surgical shock without extreme external bleeding. This is what we would expect if we regard surgical shock as due to bleeding into peripheral capillaries.

Conclusions.

The provisional conclusions at which we have arrived are :—

1. There is no *essential incompatibility* in the bloods of the various races of men in Egypt. There appears to be perfect mutual agreement between the transfused blood of Negro, Negro-Arab, Egyptian and Levantine races as well as that of fair-haired Turks or Circassians.

2. That we can verify the observations made in regard to the value of blood grouping in tissue transference, whether glandular blood, bone, or skin.

3. That the transfusion of blood is justified in grave urgency without preliminary blood grouping. Symptoms of incompatibility can be elicited by an *initial infusion of a small testing dose of blood.*

4. That the dangers of incompatibility of blood have possibly been exaggerated, but that incompatible blood is of no value as an oxygen-carrier, though good may result from the vital substances contained in it.

5. That we can also verify the observations made elsewhere as to the stimulation of blood-forming tissues to the resumption of their function, particularly in the persistent grave anæmias of bilharziasis and ankylostomiasis.

6. That blood transfusion is of value in surgical shock.

7. That there is possibly a great future for blood transfusion in the treatment of deficiency diseases.

[6] Quoted by Alexander Fleming and A. B. Porteous, THE LANCET, 1919, i., 973.

is no system of tooth-brushing, even with a twig, among the labouring classes. It may be more than a coincidence that goitre appears at the age when teeth become septic and gums swollen and inflamed.

The pathology of the goitres of Egypt exhibits no essential difference either in gross naked-eye appearance or in histological structure from that described in Western Europe. We can recognise all the histological differences described by Plummer.[4]

The diet of the rural population can hardly be held responsible for the incidence of colloid goitre or adenomata, though it may quite easily influence the non-development of disorders of secretion of the thyroid gland. It is almost entirely vegetarian. Meat is usually eaten once only in the week; and goat or mutton is the meat of choice. Swine flesh, as in all Moslem countries, is forbidden. So is alcohol in any of its forms, though, in the cosmopolitan towns, there is now a certain laxity in this respect. Cheese, milk, eggs, beans, spinach, and butter or oil form a large proportion of the daily diet. Onions are a constant feature of everyday food; so also, but to a lesser extent, is garlic. Fruits, such as dates, fresh figs, apricots, and water melons, are eaten in the summer months. There is no method of preserving meat by canning or smoking, or salting or drying in the sun. Nor is any chemical means employed to this end. Tinned or frozen or chilled meat is never eaten except in the towns.

The conclusions to which we have arrived in regard to the incidence of colloid goitre in Egypt are that it is almost entirely due to the polluted water-supply of the non-riparian villages. We suggest that one reason for the comparative non-development in men is possibly due to the fact that they depend less on the polluted village well and stored water than the women, for men in their field work drink from comparatively clean wells and irrigation channels. We do not feel that the universal parasitic diseases of Egypt, bilharziasis, ankylostomiasis, and ascaris, affecting as they do the men far more than the women, have any influence upon the development of diseases of the thyroid gland. Kocher and McCarrison have drawn attention to the influence of infected water-supplies.[5] [6]

Explanation of Development of Hyperthyroidism and Cretinism in Egyptian Towns.

But we are of opinion that there are many factors which may explain the absence of disorder of secretion of the thyroid; they may also supply an explanation for the rapid development of exophthalmic goitre and of cretinism in the first generation of Egyptians who migrate to the cities of Egypt.

These factors are:—

1. The diet of the fellaheen, which is almost entirely vegetarian and of a high vitamin content. In the cosmopolitan cities, however, the adoption to some extent of European food and cooking has brought with it a liability to European diseases. Thus gastric ulcer, duodenal ulcer, gall-stones, appendicitis, and intestinal cancer are found almost entirely in the Egyptian urban dweller.[7]

2. The extreme rarity of nervous diseases, either functional or acquired, among the agricultural population of Egypt. The incidence of these disorders, however, is becoming more common now among the town-dwelling intelligentsia.

3. The complete absence of intestinal stasis or of any of the subjective nervous phenomena associated with this condition among the fellaheen. Evidences of this condition with hypochondriasis and valetudinarianism can now be observed in the urban districts.

4. The essential difference in the psychology of the Orient from that of England or America. There are here no suppressed emotions or complexes; we believe that the free liberation of all the great emotions is of much importance in the consideration of Graves's disease and its comparative absence in Egypt.

5. The absence of strain and stress over financial affairs. There is great poverty; but there is no great uncertainty as to crops in Egypt. The price of cotton, parasitic diseases of the crops, and the risk of cattle poisoning cause some anxiety. But the savings of the fellaheen are invested in land or cattle, and not in such fluctuating speculations as stocks or shares or cotton futures. He may worry about the price he gets for his cotton; but the fellah never sells cotton that he does not possess. The Nile flood saves him from all anxiety in regard to seasons; and his buffalo is immune to cattle plague and to tubercle. The fellah is a fatalist; but there are nowadays many anxiety neuroses among the urban population that has not yet adapted itself to the rapid development of modern civilisation.

6. The simple uncomplicated lives led by the country people. The industrial revolution of the past century and the introduction of machinery have not altered their lives to any great extent. Yet owing to the exigencies of employment, or Government service, or education they may at one step pass from twelfth century village life to the bustle and noise of twentieth century Cairo, from the village street where the donkey is the swiftest mode of progression to the taxi-cab. We believe that it is these aspects of civilisation that are responsible for the development of hyperthyroidism in the towns.

7. The high infant mortality, 40–50 per cent., in the first year of life. Cretins in all probability would not survive.

8. The endocrine balance of the Egyptians. All disorders of internal secretion, with the exception of true diabetes, are rare. As in all the pigmented races that we have examined at autopsy the suprarenal capsule is noticeably much larger than in Western Europeans. The average weight of the Egyptian suprarenal capsule, from a series of 200 autopsies performed by the late Prof. Ferguson, when all fat has been dissected off, is 5 g.; of the European 3·5 g. We venture to bring this suggestion forward merely as a hypothesis, the justification for which rests in the fact that it indicates a line for future investigation.

NOTES ON SUPRARENAL AND PANCREATIC GRAFTING.

By F. C. PYBUS, M.S. Durh., F.R.C.S. Eng.,
ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

The notes of four cases dealing with the above subject, here recorded, were communicated to the International Society of Surgery at the London meeting last year. The first two cases represent attempts to cure Addison's disease by homoplastic grafting.

Seeing that the use of extracts of the suprarenal glands has failed to give relief in this disease, the only rational remedy seemed to be that of grafting. As heteroplastic methods have been tried and failed, the homoplastic method appeared well worthy of trial. The difficulty of such methods, of course, is in obtaining a suitable donor.

Suprarenal Grafting.

Case 1.—The patient, a man aged 40 years, and a miner by occupation. The illness commenced in September, 1915, with occasional vomiting, accompanied by gradual weaknes shortness o so that in a few months he became ble to wall n a few yards. At the same time colour ch he became obviously pigmented.

[6] Mc supra.

[7] Dolbey, R. V., and Incidence in Egypt, The Lancet, 1

He was admitted to hospital, where he was diagnosed as a case of Addison's disease, and was later discharged without any relief being effected. He came under my care in February, 1916, with marked asthenia, a general bronzing, a systolic blood pressure of 110 mm. Hg, and a blood picture closely resembling that of pernicious anæmia, the red count numbering 2,200,000 cells. The nature of the disease was explained to him and the proposed treatment, which he agreed to accept. He was admitted to hospital, and on March 2nd, 1916, a suitable donor was found. This was a healthy young man who had sustained a fractured spine in a colliery accident, and was almost moribund on admission. He died during the morning, and was brought immediately to the anteroom of the theatre, where, with due precautions, the suprarenal glands were removed. The recipient was already under an anæsthetic (nitrous oxide and oxygen), and the glands, within a few minutes of their removal, after being split into two halves along the natural line of cleavage in the centre of the medulla, were inserted subcutaneously, one portion beneath the breast, the remaining portion in each supraclavicular fossa. The wounds healed by first intention, and he was discharged from hospital 10 days after the operation, and was well enough to take a train journey and after this walk five miles to his own house.

Further History.—June, 1916, much improved; June, 1917, has worked one year at light work; June, 1918, has worked one year full work in the mine. By six months after the operation the pigmentation had entirely disappeared. In July, 1918, the symptoms returned. He began to become weak and the pigmentation again appeared.

The second operation was performed in 1919, when only one-half of a gland obtained by the same method was inserted into the supraclavicular fossa. A careful examination of this site was made, but no trace of the previous graft was found. In 1920 he remained in much the same condition; in 1921 he improved, and has been earning his livelihood for the past three years as a hawker.

At the present time he is slightly pigmented, the blood picture is normal, the blood pressure 130–175 mm. Hg.

Remarks.—Although this patient cannot be said to be in the best of health, he has been seen by most of my colleagues, who have agreed as to the diagnosis. The case was not published before as it was decided to do another in order further to test the results.

CASE 2.—A woman aged 25, with typical Addison's disease; blood pressure 60 mm. Hg. She was operated on on July 7th, 1922, the grafts being supplied by a male donor, whose blood tests revealed him to belong to the group of universal donors. The operation was carried out satisfactorily and the wound healed, the blood pressure for the next few days rising to 80 mm. Hg. This improvement was not maintained, the grafts appeared to absorb in about ten days, and the patient died some weeks later.

Pancreatic Grafting.

The two other cases represent attempts to relieve diabetes by pancreatic grafting. The experimental work and pathological findings pointed to the pancreas being at fault in a considerable number of cases at least, while experimental work showed that pancreatic grafts could live in a new environment. As the injection of ordinary pancreatic extract failed in its purpose, it was thought worth while to attempt homoplastic grafting in two very severe cases that were likely to end fatally in any case.

The first patient, a man of 37, the second, a man of 32, both with grave and intractable diabetes, were grafted in July, 1916, from a male donor, the grafts being obtained immediately after death by accident. The gland was divided into thin slices, four portions being placed in the subcutaneous tissue of the abdominal wall. In one case two grafts became infected and discharged out, and in the other two degenerated, although the wound healed over them. It had subsequently to be opened to allow of the discharge of the graft and surrounding liquefied tissue. In one of these cases temporary diminution of the sugar excretion was noted, but in both cases the graft failed to relieve the diabetes. One case terminated fatally three months afterwards, the other after three years.

Not much can be said about the principles of grafting, but it seems that until we are able to understand them (and I feel we do not understand them at present, especially the chemical factors), then we must continue to fail in such operations, although they may appear the most rational treatment for the diseases for which they were attempted.

Clinical and Laboratory Notes.

EUNUCHOIDISM IN SISTERS.

By IRENE YATES, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ELIZABETH GARRETT ANDERSON HOSPITAL.

IN his book on endocrine diseases Falta says[1]: "Eunuchoids we term, according to Tandler and Grosz, individuals who, without being castrated, entirely simulate in their clinical manifestations the true eunuch type, or at least are extraordinarily similar to it. They are either tall, or if complications are absent, at least not stunted in growth; they show the typical fat-distribution of eunuchs, and eventually pronounced obesity; the epiphysial junctures persist abnormally long, the skeletal dimensions are characterised by an especial length of the extremities, and furthermore, the individuals show a definite psychical habitus. Finally, there is found a more or less pronounced disturbance of development of the genitalia with faulty development of the secondary sexual characteristics."

F. M. and A. M., sisters, aged 24 and 22 respectively, were sent to the Elizabeth Garrett Anderson Hospital for primary amenorrhœa. Both sisters had walked at one year; at school they were normal in height, but had grown rapidly between 14–18, since when neither had grown much. There are two others in the family, the youngest, a boy aged 17, is tall; and a sister aged 19, who is normal in height and menstruates regularly. The father is tall; the mother, of normal height, has a normal menstrual history.

The eldest, F. M., height 5 ft. 10¾ in., weight 9st. 1½ lb., is very intelligent, has a feminine voice and appearance, a boyish manner, and rather a sallow complexion. There is no development of breasts, axillary or pubic hair. The external genitalia are of the infantile female type. No hymen is present. There is a wide opening into the vagina, which is a pouch about ¾ inch in height, the uterus and ovaries are not palpable. The measurement from the umbilicus to the ground is 70 per cent. of the total height instead of the usual 60 per cent., the legs being abnormally long in proportion to the height. The upper limbs are also abnormally long. The left field of vision is normal, the right shows a slight contraction (10°) on the temporal side, both fundi are normal. The urine is normal in quantity and constituents. The sugar tolerance is normal. Systolic blood pressure is 118 mm. Hg. Wassermann reaction is negative. X ray examination shows the pituitary fossa to be normal in size and outline, the epiphyses of the long bones to be still separate from the shaft, the hands to be of the male, and the pelvis of the female type.

A. M., height 6 ft. 1½ in., weight 11 st. 1¾ lb., is intelligent, has a feminine voice, appearance and manner, and a fair skin. There is some development of the breasts; palpation suggests this is fat and not glandular tissue. There is no axillary hair, and only a few pubic hairs are present. There is an abnormal deposit of fat in the abdominal wall. The external genitalia are of the infantile female type; a hymen is present; the opening in the vagina is wide, the latter being a cul-de-sac about 1 inch in height, at the top of which is a small nodule about the size of a pea, which appears to have no opening. The uterus and ovaries are not palpable. The arms and legs are again long in proportion to the height, the measurement from the umbilicus to the ground being 66 per cent. of the total height. The fields of vision and fundi are normal. The Wassermann reaction is negative. Systolic blood pressure is 120 mm. Hg. The urine is normal. The sugar tolerance test (made by Miss E. M. Martland, M.B., B.S.) gave an abnormal result. Blood-sugar per cent. (fasting), 0·103; after half an hour, 0·215; after one hour, 0·204; after one and a half hours, 0·199; after two hours, 0·125. No glycosuria was detected during the test.

X ray examination showed the pituitary fossa to be normal in size and outline, the bones of the hands and pelvis to be of the female type, and the epiphyses of the long bones to be still separate from the shaft.

It is difficult to be certain of the psychical habitus of these girls; both say the male sex has little attraction for them. The younger has all the physical characteristics of a eunuchoid as given in the above definition: the elder has all except the is no system of tooth-brushing, even with a twig, among the labouring classes. It may be more than a coincidence that goitre appears at the age when teeth become septic and gums swollen and inflamed.

---

[1] Transl. Meyers, Philadelphia, 1915.

The pathology of the goitres of Egypt exhibits no essential difference either in gross naked-eye appearance or in histological structure from that described in Western Europe. We can recognise all the histological differences described by Plummer.[4]

The diet of the rural population can hardly be held responsible for the incidence of colloid goitre or adenomata, though it may quite easily influence the non-development of disorders of secretion of the thyroid gland. It is almost entirely vegetarian. Meat is usually eaten once only in the week; and goat or mutton is the meat of choice. Swine flesh, as in all Moslem countries, is forbidden. So is alcohol in any of its forms, though, in the cosmopolitan towns, there is now a certain laxity in this respect. Cheese, milk, eggs, beans, spinach, and butter or oil form a large proportion of the daily diet. Onions are a constant feature of everyday food; so also, but to a lesser extent, is garlic. Fruits, such as dates, fresh figs, apricots, and water melons, are eaten in the summer months. There is no method of preserving meat by canning or smoking, or salting or drying in the sun. Nor is any chemical means employed to this end. Tinned or frozen or chilled meat is never eaten except in the towns.

The conclusions to which we have arrived in regard to the incidence of colloid goitre in Egypt are that it is almost entirely due to the polluted water-supply of the non-riparian villages. We suggest that one reason for the comparative non-development in men is possibly due to the fact that they depend less on the polluted village well and stored water than the women, for men in their field work drink from comparatively clean wells and irrigation channels. We do not feel that the universal parasitic diseases of Egypt, bilharziasis, ankylostomiasis, and ascaris, affecting as they do the men far more than the women, have any influence upon the development of diseases of the thyroid gland. Kocher and McCarrison have drawn attention to the influence of infected water-supplies.[5] [6]

Explanation of Development of Hyperthyroidism and Cretinism in Egyptian Towns.

But we are of opinion that there are many factors which may explain the absence of disorder of secretion of the thyroid; they may also supply an explanation for the rapid development of exophthalmic goitre and of cretinism in the first generation of Egyptians who migrate to the cities of Egypt.

These factors are:—

1. The diet of the fellaheen, which is almost entirely vegetarian and of a high vitamin content. In the cosmopolitan cities, however, the adoption to some extent of European food and cooking has brought with it a liability to European diseases. Thus gastric ulcer, duodenal ulcer, gall-stones, appendicitis, and intestinal cancer are found almost entirely in the Egyptian urban dweller.[7]

2. The extreme rarity of nervous diseases, either functional or acquired, among the agricultural population of Egypt. The incidence of these disorders, however, is becoming more common now among the town-dwelling intelligentsia.

3. The complete absence of intestinal stasis or of any of the subjective nervous phenomena associated with this condition among the fellaheen. Evidences of this condition with hypochondriasis and valetudinarianism can now be observed in the urban districts.

4. The essential difference in the psychology of the Orient from that of England or America. There are here no suppressed emotions or complexes; we believe that the free liberation of all the great emotions is of much importance in the consideration of Graves's disease and its comparative absence in Egypt.

5. The absence of strain and stress over financial affairs. There is great poverty; but there is no great uncertainty as to crops in Egypt. The price of cotton, parasitic diseases of the crops, and the risk of cattle poisoning cause some anxiety. But the savings of the fellaheen are invested in land or cattle, and not in such fluctuating speculations as stocks or shares or cotton futures. He may worry about the price he gets for his cotton; but the fellah never sells cotton that he does not possess. The Nile flood saves him from all anxiety in regard to seasons; and his buffalo is immune to cattle plague and to tubercle. The fellah is a fatalist; but there are nowadays many anxiety neuroses among the urban population that has not yet adapted itself to the rapid development of modern civilisation.

6. The simple uncomplicated lives led by the country people. The industrial revolution of the past century and the introduction of machinery have not altered their lives to any great extent. Yet owing to the exigencies of employment, or Government service, or education they may at one step pass from twelfth century village life to the bustle and noise of twentieth century Cairo, from the village street where the donkey is the swiftest mode of progression to the taxi-cab. We believe that it is these aspects of civilisation that are responsible for the development of hyperthyroidism in the towns.

7. The high infant mortality, 40–50 per cent., in the first year of life. Cretins in all probability would not survive.

8. The endocrine balance of the Egyptians. All disorders of internal secretion, with the exception of true diabetes, are rare. As in all the pigmented races that we have examined at autopsy the suprarenal capsule is noticeably much larger than in Western Europeans. The average weight of the Egyptian suprarenal capsule, from a series of 200 autopsies performed by the late Prof. Ferguson, when all fat has been dissected off, is 5 g.; of the European 3·5 g. We venture to bring this suggestion forward merely as a hypothesis, the justification for which rests in the fact that it indicates a line for future investigation.

NOTES ON
SUPRARENAL AND PANCREATIC GRAFTING.

BY F. C. PYBUS, M.S. DURH., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY,
NEWCASTLE-UPON-TYNE.

THE notes of four cases dealing with the above subject, here recorded, were communicated to the International Society of Surgery at the London meeting last year. The first two cases represent attempts to cure Addison's disease by homoplastic grafting.

Seeing that the use of extracts of the suprarenal glands has failed to give relief in this disease, the only rational remedy seemed to be that of grafting. As heteroplastic methods have been tried and failed, the homoplastic method appeared well worthy of trial. The difficulty of such methods, of course, is in obtaining a suitable donor.

Suprarenal Grafting.

CASE 1.—The patient, a man aged 40 years, and a miner by occupation. The illness commenced in September, 1915, with occasional vomiting, accompanied by gradual weakness and shortness of breath, so that in a few months he became unable to walk more than a few yards. At the same time his colour changed, and he became obviously pigmented.

[7] Dolbey, R. V., and Mooro, A. W.: The Incidence of Cancer in Egypt, THE LANCET, 1924, i., 587.

tion the condition of the patient did not warrant an investigation of the blood-supply of the floating bowel. Its appearance was pale and led one to believe that the blood-supply was not as fine as that of the rest of the bowel. Since operation, however, the patient has remained well and the blood-supply, however curtailed, seems to be sufficient.

The fact that with the cæcum floating the point of maximum tenderness was over McBurney's point is an example of pain referred to the ninth and tenth thoracic nerves.

Reviews and Notices of Books.

OBSTETRICS.

A Text-book for the Use of Students and Practitioners. Fifth enlarged and revised edition. By J. WHITRIDGE WILLIAMS, Professor of Obstetrics, Johns Hopkins University. London and New York: D. Appleton and Company. 1923. Pp. 1076. 40s.

FOR 20 years this excellent text-book has been before the profession, and each succeeding edition has served but to increase its value and the esteem in which it is held. As a monument of careful observation and record it has few equals, and its importance is enhanced by the clear judgment and care which the author exercises throughout.

To the practising obstetrician the work is essential, and in the fifth edition the practitioner will find a useful and conservative guide to the modern treatment of all obstetric difficulties with which he may be confronted. All recent writings of importance have received consideration, and the march of progress is duly emphasised. At the same time Prof. Whitridge Williams issues a strong and, we think, justified plea in many directions for conservatism. He draws attention to the fact that recent American statistics have shown a definite rise in the puerperal death-rate in that country, and that child-birth was actually more dangerous in America in 1921 than in 1916. Further, this death-rate is greater in urban than in rural communities. He attributes this to the fact that many practitioners have been led astray by the teaching of those who regard labour as a pathological rather than a physiological process, and he thinks that unjustifiable interference is frequently undertaken by those who do not fully appreciate the risk involved. It is interesting to note that an inquiry by a committee of the Massachusetts State Medical Society into the puerperal death-rate showed during the year 1921 that after puerperal infection Cæsarean section ranked in America as the most frequent cause of death from child-birth. It is but natural, therefore, that the author has some strong remarks to make not only against the abuse of this operation, but against obstetric meddling in general. In fact, the keynote of conservatism is noticeable throughout the volume. We welcome this expression of moderation, coming as it does at an epoch when excess of operative zeal is tending in some quarters to displace the true art of obstetrics, to the detriment, we fear, of maternal well-being.

The book follows the general arrangement of its predecessors, but each chapter has been thoroughly overhauled and brought up to date. There is, for example, a full and instructive criticism of Potter's monograph on the "Place of Version in Obstetrics," in which the author adduces very cogent arguments against the general acceptance of Potter's teaching. Recent methods of diagnosis such as the use of X rays in the investigation of pelvic contraction and fœtal positions are discussed, and full references given. In fact, the unusually complete bibliography appended to each chapter, indeed almost to each paragraph, is a feature of the book which makes it invaluable as a work of reference. The details of obstetric management which the author advocates are, generally speaking, those in use in this country. A few variations occur. For example, Prof. Williams appears to favour the use of de Ribes's bag in preference to bipolar version in the treatment of placenta prævia, chiefly, as he says, in the interest of the child. Again, when discussing post-partum hæmorrhage no mention is made of bimanual compression of the uterus, a method which is always available and usually effective. The book has been enriched by several new illustrations well reproduced.

NOUVEAU TRAITÉ DE MÉDECINE.

Fascicule XI.: Pathologie de l'appareil respiratoire (*nez, larynx, trachée, bronches, poumons*). By FERNAND BEZANÇON et S. I. DE JONG, H. BOURGEOIS, HUTINEL et PAISSEAU, P. HARVIER, L. RIBADEAU-DUMAS. Paris: Masson et Cie. Pp. 636. Fr.45.

WE have in previous reviews had occasion to call attention to the general excellence of the system of medicine, of which the present is the eleventh volume. This high standard is here maintained, the logical arrangement and clear description of physical signs, morbid anatomy, and general pathology being in the best tradition of French medical writers. The relegation of pneumonia to the volume dealing with infections leaves a gap in this volume, but the field here covered is enormous. Many English readers will cavil at the description of asthma by Prof. F. Bezançon and S. I. de Jong, who, whilst making some reference to protein-sensibility, continue to deal with the disease mainly from the respiratory point of view. Even hay fever is said to be a disease, occurring chiefly in America, and the modern conception of asthma as a toxic idiopathy is almost ignored.

We commend the volume as a corrective to insularity as well as on account of its completeness and admirable style.

PHYSICAL DIAGNOSIS.

Eighth edition. By RICHARD C. CABOT, M.D., Professor of Medicine in Harvard University; formerly Chief of the West Medical Service at the Massachusetts General Hospital. London: Baillière, Tindall and Cox. With 6 plates and 279 illustrations. Pp. 536. 25s.

THE new edition of this well-known book maintains the high standard of its predecessors, and should tend to make it still more popular. Every medical student should possess a copy. The minutiæ of examination are clearly described, and the proportion of space given to such fundamentals as the technique of percussion and auscultation is adequate. A notable change from former editions occurs in Chapter XVIII., where Dr. Cabot has completely revised his views on emphysema. "Till 1921," he writes, "I thought I could recognise emphysema. The following facts have disillusioned me. In 12 cases diagnosed as emphysema at the Massachusetts General Hospital, only three showed any emphysema post mortem. On the other hand, of the 153 cases demonstrated post mortem, only seven were recognised in life." "I know to-day nothing about the physical signs of emphysema," he says later, and proceeds to write an illuminating chapter on the "barrel chest" distinguished alike by its clarity of description and absence of dogmatism. The plates and illustrations are admirably reproduced.

PRACTICAL ELECTROTHERAPEUTICS AND DIATHERMY.

By G. BETTON MASSEY, M.D., Fellow and former President of the American Electrotherapeutic Association. London: J. and A. Churchill. 1924. Pp. 401. 21s.

IN the first nine chapters of this book the author deals with the various currents used in medical electricity. He describes their nature, the methods of producing them, and their action on the body. In the remaining chapters (X. to XIX.) electrical treatment of various diseases and symptoms is abnormal fat deposit. I consider that the data in both cases justify their classification as eunuchoids. Eunuchoidism in females is extremely rare, and I find no record of its occurrence in sisters.

My thanks are due to the various members of the staff of the hospital who helped in the investigations, and to Mr. Ulysses Williams who kindly took the X ray photographs.

NOTE ON AN UNUSUAL CAUSE OF DEATH IN SUBACUTE INFECTIVE ENDOCARDITIS.

By M. Weinbren, B.Sc. (South Africa), M.R.C.S. Eng.,

RESIDENT MEDICAL OFFICER, MINISTRY OF PENSIONS HOSPITAL, ORPINGTON;

AND

The late T. H. Jamieson, M.D., M.R.C.P. Edin.,

LATE VISITING PHYSICIAN TO THE HOSPITAL.

In view of the unusual termination the following case is of interest.

W. L., aged 35, enlisted in 1908, and was discharged in January, 1919. His invaliding disability was V.D.H. with aortic insufficiency, the date of origin being uncertain, and he gave a history of malaria contracted in East Africa in 1914.

Condition on Admission.—When admitted into Orpington on May 5th, 1923, he was anæmic and his general condition was poor. The apex beat was in the fifth space, just beyond the nipple line, and the right border of the heart at the right edge of the sternum. A loud systolic bruit could be heard all over the chest, loudest in the mitral area, and a faint diastolic murmur could be heard in the mitral area and along the left border of the sternum. The liver was enlarged to about one inch below the costal margin and the spleen was palpable on inspiration. There was no œdema of the legs and no signs of fluid in the abdomen. During the period in hospital he ran an intermittent temperature between 100° and 97·5° F., and his pulse varied between 104 and 84. A Wassermann test proved negative. Blood cultures also proved negative. The urine showed a good trace of albumin, a few blood casts, and a fair number of pus cells.

On June 27th he complained of a sudden stab of pain in the left chest, radiating from the left costal margin to the left clavicle, and recurring with every inspiratory movement. There was considerable tenderness and rigidity below the left costal margin, and a to-and-fro rub was detected over the splenic area. His pulse was 98 and temperature 97·8° F. Splenic infarct was diagnosed. The patient steadily improved, the pain, rigidity, and tenderness passing off at the end of a week. The spleen was then found to be more easily palpable than on admission.

On July 16th, although feeling much brighter during the day, he complained of a sudden attack of giddiness about 7 P.M. and died within 15 minutes. Autopsy showed the heart to be enlarged. There was no pericarditis and no naked-eye changes in the muscle wall. There were few firm vegetations on the aortic valve and there were vegetations on the mitral valve, which was greatly thickened and had an arc ulcerated away from the anterior flap. The aorta was healthy. On opening the abdomen it was found that the whole peritoneal cavity was filled with blood clot, and post-peritoneal blood staining was seen on the left side of the vertebral column adjacent to the spleen and left kidney. An attempt was made to trace the source of the hæmorrhage. No aneurysm was found and no ulceration or any change of note in the stomach or intestines. The kidneys were enlarged, pale, fatty, and had a flea-bitten appearance. On removing the spleen (which was enlarged, weighing 19½ oz.) a transverse yellow infarct, which on section was seen to be lined with a dark red layer, showing that it was of recent origin, was found at the upper pole. Quite separate from the infarct, on the diaphragmatic surface of the spleen, was a discoloured area about three inches in largest diameter. The capsule of the spleen, both serous and fibro-elastic coats, was detached from the pulp, and it was evidently from this area that the hæmorrhage had taken place, the blood having oozed into the retro-peritoneal tissue and not through the hilum or lieno-renal ligament. On section, a large cavity was seen in the centre of the spleen and the tissue round it, microscopically, was found to be quite necrotic.

The cause of death was evidently a blood-vessel giving way in the necrotic portion of the spleen, which was probably a soft infarct. The capsule of the spleen tearing with the increased pressure allowed the patient to bleed to death. We have been unable to trace any record of a similar termination to a case of subacute infective endocarditis.

The Director-General of the Medical Services of the Ministry of Pensions kindly gave us permission to publish the case.

MOBILE ASCENDING AND TRANSVERSE COLON.

By T. A. B. Harris, M.B., B.S. Melb.

The following case is of interest, both on account of the infrequency of the condition and of the trouble it may give the surgeon.

E. B., female, aged 16, was admitted to Ipswich Hospital, Queensland, on June 13th, 1923. There was a history of three separate attacks of sudden pain in the lower abdomen, settling down into the right iliac fossa, with constipation, fever, dry tongue, and rapid pulse. On admission she was definitely tender over McBurney's point. A diagnosis of chronic appendicitis was made, and an appendicectomy performed on June 14th. The cæcum, ascending and transverse colons were located on the left side lying parallel to the descending colon, and entirely covered with small bowel. The appendix showed signs of recent inflammation and was removed. The cæcum, ascending colon, and half the transverse colon were entirely free and had no attachment and no mesentery. The bowel was pale in colour, and the great omentum was very short (2 inches). No attempt was made to anchor the floating bowel, as the patient was beginning to feel the effect of the excessive manipulation necessary to locate the appendix. She made an uninterrupted recovery.

Comments.

In early fœtal life the colon lies entirely to the left side of the abdomen attached by a mesentery to the posterior abdominal wall. With the elongation and growth of the small intestine that portion which eventually forms the cæcum, ascending and transverse colon swings to the right side, and at the fourth month of extra-uterine life the cæcum is found immediately below the liver (F. Treves). From this time the large intestine grows in length and size, and takes up the position found in the normal adult. G. E. Waugh[1] describes cases of irregularities of the colon under four main heads: (1) Undescended cæcum. (2) Mobile ascending colon and cæcum in which it has descended, but has retained its primitive mesentery. (3) Mobile ascending colon and cæcum in which it has descended and has been fixed, but has acquired a false mesentery. (4) Two cases in which the whole of the colon lay in the left iliac fossa, having made no attempt at rotation from its primitive position to the right side of the body. In one case—a girl, aged 11 years—chronic appendicitis had been diagnosed; in the other—a woman, aged 22 years—treatment for gastric ulcer had been given for nearly two years before operation. At operation no disease of the appendix or stomach was present in either case. Radiograms of barium meals, taken previously to the operations, had failed signally to indicate the presence of the abnormality in both cases—in fact, the right colon appeared to be in a more or less normal position in the right iliac fossa and pelvis. A primitive dorsal mesentery was present along the whole length of the alimentary tract from duodenum to rectum.

In this case there seem to be two alternative explanations. It may be that the colon had failed to rotate to the right side, while developing normally as regards shape and size, and together with this had lost its primitive mesentery. The other explanation may be that it has developed in a normal manner, but has failed to become anchored to the posterior abdominal wall and has lost its primitive mesentery, which is the more probable explanation. At opera-

[1] Waugh, G. E.: Brit. Jour. Surgery, January, 1920; Brit. Med. Jour., November, 1922.

Prof. J. Bauer (Hamburg), and Prof. M. Stoob (Berne), but also for the coloured photographs of the rashes and the lesions of the exanthemata, which are models of accuracy. The third volume deals with diseases of the digestive, respiratory, and circulatory systems, and achieves a level as high as that of its predecessor. If it is not invidious to select certain articles for special mention, attention might be directed to those by Prof. E. Feer (Zurich) on congenital pyloric stenosis, and by Prof. St. Engel (Dortmund) on diseases of the lungs. Too big for the needs of general practice, this handbook should certainly be on the shelves of all medical libraries.

Johannes de Ketham.

The Fasciculus Medicinæ of Johannes de Ketham, Alemanus. Facsimile of the first (Venetian) edition of 1491. With Introduction by Karl Sudhoff. Translated and adapted by Charles Singer. London: Humphrey Milford, Oxford University Press; Milan: R. Lier and Co. 1924. Pp. 56 and 13 plates. 46*s.*

This sumptuous production is of interest as the first printed general manual of professional information for medical men; it includes not only treatises on medicine, but also upon midwifery and surgery. Prof. Sudhoff gives reasons for thinking that Ketham is really a variant of Kircheim, and Johannes de Ketham was, in fact, a Swabian, Johan von Kircheim, Professor at Vienna about 1460. He compiled the Fasciculus from various manuscripts and sets of rules for medical practice which were in vogue before his time. The book opens with an account of the urine and the various diagnoses to be made from an inspection thereof; there follows an elaborate section upon bleeding, and next come a section upon gynæcology, one on generation and midwifery and a surgical section. The final section is an attempt at a short dictionary of medicine.

As an appendix is given the interesting tract of Peter of Tussignano on the plague, with rules for avoiding infection and indications for treatment. This treatise is well worth reading. In one passage in a section upon various doubtful points, he discusses the question (in the ninth doubt) as to whether monks and prisoners do not die of the plague, although he adds, "sometimes they all die, and at other times not so." The answer is as follows: Those who live in a closely guarded community are not so much exposed to infection as those outside. But if one of the community should become infected the infection rapidly spreads. It must be noted that in the Black Death of 1348–49 the mortality among the regular clergy was exceedingly high.

All those interested in medical history owe a debt of gratitude to those who have made this most interesting treatise available at a comparatively moderate cost to modern readers.

Quantitative Organic Microanalysis.

By Fritz Pregl, D.Sc., Ph.D., Professor of Medicinal Chemistry; Principal of the Medico-Chemical Institute of the University of Graz. Translated by Ernest Fyleman, B.Sc., Ph.D., F.I.C. London: J. and A. Churchill. 1924. Pp. 190. 12*s.* 6*d.*

Dr. Pregl's work on micro-analysis is too well known to require introduction to anyone conversant with continental chemical literature. It will be remembered that he evolved the technique for the ultimate analysis of very small quantities of organic compounds. By his method carbon and hydrogen can be determined accurately in quantities weighing 7 to 13 milligrammes, whilst sulphur and halogens can be estimated in even smaller quantities. Up to the present detailed accounts of these techniques could only be obtained from German publications, such as Abderhalden's *Biochemischen Arbeitsmethoden* and Weil's *Methoden*. The present volume is therefore the only account of micro-analytical methods published in English. The descriptions are full of such minute details as to astonish any reader unaccustomed to German analytical methods, but these details are very necessary if the technique is to be carried out efficiently.

With the increasing importance of biochemistry, and particularly with that section dealing with chemotherapy, the need for micro-analysis has become urgent, and the volume will be welcomed. The translator deserves praise for his careful work.

The Conquest of Constipation.

By William S. Walsh, M.D. London and Toronto: J. M. Dent and Sons, Ltd. Pp. 265. 5*s.*

This book contains a certain amount of scientific fact in a mass of popular description. For the medical reader it will have little interest, and for the lay reader we fear that it will tend to accentuate those psychic effects of constipation which may be so disastrous. The author writes fluently, and his book is well printed and of a useful size.

JOURNALS.

Biochemical Journal. Vol. XVIII., No. 384. 1924.—This issue commences with an obituary notice of the late Prof. Tigerstedt, in which his work is reviewed. The majority of the papers deal with the chemical side of the subject, but there are some of direct clinical interest.—In her paper entitled Calcium Content of the Blood During Pregnancy, Part II., Miss S. T. Widdows describes the extension of her work to pathological cases. In a previous paper the calcium content was found to vary with the stage of pregnancy. Thus, there is a drop in the calcium content after the eighth month. In abnormal cases, such as those of albuminuria, eclampsia, the fall occurs earlier, at about the fourth month of gestation.—K. Tallerman, in his communication on the Type of Sugar Excreted in the Urine of Normal Persons, describes experiments designed to throw light on the nature of the blood-sugar. He reviews very briefly the current views concerning α, β, and γ glucose, and refers to the work of Winter and Smith, who stated that sugar in normal blood was in the γ form. It will be remembered that they claimed that the sugar of diabetic blood was in the β form, and that insulin converted the β to the γ form. Tallerman calls attention to the criticisms of Hewitt on the drastic methods of heating the blood prior to polarimetric observation, and suggests that examination of the urinary sugar might clinch the matter. From a series of careful experiments Tallerman concludes that the sugar excreted by normal persons after an injection of phloridzin is in the α β form. Also that passed by diabetics wus not γ glucose. He therefore concludes that it is extremely unlikely that γ glucose is present in the blood or urine of normal persons.—H. W. Dudley describes the preparation of insulin from the pancreas of cod fish. The islets were dissected out on the trawlers and were preserved in aqueous solutions of picric acid. By means of an extraction process, described in the paper, large yields of insulin were obtained. Thus, even after the fish had been dead for 24 hours, a yield of 13·12 rabbit units was obtained. The author has worked out that the islet tissue of the cod fish contains about ten times as much insulin, weight for weight, as the human pancreas.—There are also papers on rickets and vitamins by E. M. Luce and R. Robinson and E. M. Soames.

British Journal of Children's Diseases. Vol. XXI. July–September.—Dr. Sydney A. Owen and Dr. A. Neave Kingsbury contribute a paper on the described. Dr. Massey devotes a special chapter, the longest in the book, to the subject of the treatment of malignant growths by zinc ions, a method to which he has devoted many years of study. Full details of technique used by him are included, the results being illustrated by photographs of the patients before and after treatment. The cases figured have been kept under observation for not less than two years, and, judging by the illustrations and descriptions, the results appear to be excellent. Currents of 2000 or even 3000 milliampères were used in some cases, and by confining them to the growth and its immediate vicinity the dangers which would attend the uncontrolled use of currents of this kind and strength are avoided. Currents of this strength produce enough heat to coagulate the tissue proteins. The destruction of the growth is caused, therefore, by heat as well as electro-chemical cauterisation. In another chapter the author describes a method of treating tuberculous glands and cystic goitre by zinc ions. The chapter entitled Electricity in Industrial and Reconstructive Surgery deals almost entirely with the testing of electrical reactions. The method described is that in which the faradic and galvanic currents are used, but there is a short account, quoted from another writer, of the condenser method. Dr. Massey also quotes an account, by another author, of the "progressive galvanic test." This is really a form of treatment in which denervated muscles are made to contract by a selective stimulus which does not cause simultaneous contraction of muscles with intact nerve-supply. In this account a wrong impression is given of the meaning of the term "chronaxic."

This book will be read with interest by those who are experienced in medical electricity, especially the section on the treatment of malignant growths. It is less suitable for the beginner as the descriptions given in certain parts, more particularly those dealing with physics and physiology, are insufficiently clear and not always free from mistakes. Thus in the account of the effects of the direct current on the tissues the beginner might confuse cataphoresis with migration of ions. Such expressions and statements as the "soapy ions of sodium and hydrogen," the "cations of water" (p. 41), Wallerian degeneration in "nerve endings or muscle," "the neuraxon may be said to curdle" (p. 167), "the negative polar surface receives a similar blast of nitrogen" (p. 133) are loose and unscientific. On p. 41 "catophoresis" and on p. 323 "sinusodial" are misprints. The book is well illustrated.

Diabetes.

A Diabetic Manual for the Mutual Use of Doctor and Patient. Third edition. By Elliott P. Joslin, M.D., Clinical Professor of Medicine, Harvard Medical School, Boston, U.S.A. Philadelphia and New York: Lea and Febiger. 1924. Pp. 211. $2.

> "To help make the home safe for the diabetic is the object of the book."

Prof. Joslin has set out plainly all that he thinks a patient should know about the cause and treatment of the disease. As his book occupies 203 pages (including the tables) it is obvious that he thinks that the patient should know a great deal. It is equally certain that if a doctor recommends a book to a patient he should learn its contents most carefully or he will not retain the patient's confidence. The volume should fulfil its purpose as the details are most carefully thought out. Very little is said about diabetic foods; Joslin says that those of his patients who have done best have either abstained altogether from their use or have only used a few varieties. Instructions as to the administration of insulin are clear and good; the things which the patient should know in order to save the doctor's time are very important. The food tables are very full, but are not arranged in the most convenient way as they are only given in percentages instead of in so much per ounce. The last-named practice is a great convenience for patients who only use the English weights.

Diabetes: its Treatment by Insulin and Diet. A Handbook for the Patient. By Orlando H. Petty, B.S., A.M., M.D., F.A.C.P., Professor of Diseases of Metabolism, Graduate School of Medicine, University of Pennsylvania. Philadelphia: F. A. Davis Company. 1924. Pp. 111. $1.50.

This little manual covers somewhat the same ground as Prof. Joslin's, but it is written in a less elaborate form and is suitable for patients with less education. Diabetes, above all other diseases, requires the intelligent coöperation of the patient, and books must be available for all grades. Here the greatest stress is laid on the minute details of managing the diet, weighing, and injecting insulin. The book will be of assistance as a guide to patients.

Nouveau Traité de Chirurgie.

Troisième édition. Fascicule XXIX.: Hernies. Par Maurice Patel, Professeur Agrégé à la Faculté de Médecine de Lyon. Paris: J. B. Baillière et Fils. 1924. Pp. 540. Fr.45.

A volume on a subject with which we are familiar, when it arrives from another country teaches us more than facts. We enter a new atmosphere where values differ from our own, and realise that even such a cosmopolitan subject as surgery may have a strong national bias, while we find that its methods and even its history may look quite different when seen through other eyes. Prof. Patel's book is not imposing in form and the absence of an effective index makes reference difficult. But none the less, it contains a large amount of useful information clearly arranged, and evidently represents the general teaching of the French school of surgery at the present day. The views expressed are eminently sound and practical, the pathology is clearly described, and certain suggestions made, for example, as to the origin of umbilical hernias, are of considerable interest.

It is discouraging to find almost no mention of English surgery; filigrees and darning are at least worthy of mention as resources in difficult cases. But a more painful blow is the description of the "English" truss, a contrivance which has disappeared even from instrument makers' catalogues. If, indeed, England is responsible for its invention we must plead it was more than a century ago. Workmen's compensation appears to have its difficulties in France, and there is an excellent discussion on the legal aspects of hernias. It is generally agreed that in not one case in a hundred is a hernia the real result of an accident, but the Cour de Cassation proved equal even to this difficulty and its finding on the subject is delightful. "Mais en admettant que le travail de Th. n'ait pas été la cause de la hernie, il en avait été du moins l'occasion." Apparently, if opportunity makes the thief, it also makes the hernia.

A Pædiatric Handbook.

Handbuch der Kinderheilkunde. Edited by Prof. M. von Pfaundler (Munich) and Prof. A. Schlossmann (Düsseldorf). In four volumes. Leipzig: F. C. W. Vogel. 1924. Vols. II. and III., pp. 700 each.

The second and third volumes of this monumental handbook are now published, and may well serve as a valuable mine of information to physicians specially interested in children's diseases in all lands. Opinions will naturally differ as to certain conclusions reached by the writers, but the general editorship is so good and the work is so typical of what is best in German industry that no one can fail to obtain great help by reference to such a work. The second volume deals with the infectious diseases, and is remarkable not only for the articles by Prof. B. Schick (Vienna).

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 13, 1924.

NEW REMEDIES.

FOR practitioners who began their medical careers a few decades ago the choice of drugs was practically limited to vegetable substances and chemical products, most of which had been prescribed in one form or another by their predecessors, sometimes through many generations. If some of these practitioners are of opinion that materia medica has been enlarged at too rapid a rate during the past quarter of a century, although the production of novelties was suspended in some directions during the war, their attitude is a quite reasonable one when it is based upon the feeling that mere novelty is not necessarily a recommendation. To-day inventiveness is again receiving full play in many chemical laboratories, and in the near future it is certain that many therapeutic substances which were unknown 30 years ago will claim employment in place of numerous drugs now usually employed. The inventiveness will require watching, and this was the notable lesson which emerged from the deliberations of the recent British Pharmaceutical Conference.

There is a law of economics that bad money drives good money out of circulation. We must take care lest this law apply itself to medicine. The Germans, before the war, were prominent in the art of inventing new drugs; in the huge laboratories on the Rhine hundreds of highly skilled chemists were engaged in the work of revolutionising therapeutics, and from the factories, of which these laboratories formed part, series upon series of new synthetic products were thrown on the world's markets, and it is commonly acknowledged that these German chemists rendered an inestimable service to medicine. It is known that the great anilin dye works on the Rhine exercised strict precautions before they introduced new substances to the medical profession; they utilised the means at their disposal for ensuring scientific accuracy and making clinical tests. We enjoy the results of their enterprise and research in series of products which are regularly prescribed by medical men everywhere. There are great British and American firms who work on similar lines and whose results are scrupulously checked by medical authority. There arise, of course, quacks and imitators, inside and outside Germany, whose inventiveness is restricted largely to nomenclature; selling the same thing under many names, they claim for their multiple-titled drugs virtues which the actual inventors of the substances never claim, and so help to bring into disrepute reputable goods. But having paid due respect to enterprise, we may ask the question whether it is desirable in the interests of medicine to be content with a situation which places us unreservedly in the hands of enterprising commercial houses, all of which are not equally supplied with medical information. In his presidential address to the British Pharmaceutical Conference, Mr. EDMUND WHITE said: "At the present time there is no public authority specially charged with the examination and standardisation of remedies by physiological or biological methods. There is no public laboratory where any firm or person inventing a new remedy can have such substances tried and examined, nor is there a laboratory where a pharmacist making his own preparations can have them examined by physiological methods to determine their potency." Our attention has been drawn to this position by a letter in the *Pharmaceutical Journal* from Dr. F. E. STEWART, who on previous occasions has advocated the organisation in America of some such institution as Mr. WHITE would have established.

Dr. STEWART's opinion is that a new remedy is not fitted for clinical test by physicians in hospital or private practice until "standardisation" by an official body is effected. Perhaps standardisation is hardly the *mot juste*, since it is at least doubtful if it would be possible in every case, but there is undoubtedly a great need for a central clearing-house for new medicinal substances. It is hardly fair to throw on business firms the enormous responsibility which some of them are more willing than able to shoulder. In the United States it has been suggested that new remedies should be manufactured under licence, and such a plan is now being put into practice there in connexion with the introduction of pneumococcus antibody solution under the professional control of the "Influenza Commission" set up by the Health Department of the United States Government. This is similar to the plan carried out by the University of Toronto for the manufacture of insulin, and schemes such as these are conceived on the right lines. But a more comprehensive system is needed to form a connecting link between the producers of new remedies and those who prescribe them, and such a scheme should include provision for the testing and recording of clinical experience. The grave professional difficulties arising here are clear to all our readers, but to some extent they should not be insuperable.

A CASE OF LATENT LEPROSY.

THE incubation period of leprosy has been a continual source of speculation for those who have studied this terrible disease. It has been recognised for some time past that the lepra bacillus may be dormant in the human body for a period of years; but it is from a study of those cases—and several have been recorded—which arise in countries where this disease is no longer endemic that the most accurate data are obtainable. Such a case has recently been seen in London in which a woman developed leprosy after an incubation period of eight years, but here the source of infection was easily ascertainable. The remarkable instance of extreme latency, reported by Sir NORMAN WALKER in our present issue, may well constitute a record. The incubation period in this instance must have been one of 40 years, for the patient, a Russian Jewess, had resided in Scotland for the whole of that period without exhibiting any evidences of the disease. The source of infection being unascertainable, it must be inferred that the organisms were present in her body the whole of that lengthy period. The last British leper of indigenous origin is known to have died in Shetland in 1798, and about the middle of last century an instance of a man contracting leprosy in Ireland was recorded by the late Sir HAWTREY BENSON. This man contracted the disease, as was made abundantly clear, by wearing the cast-off clothing of his brother who had died of leprosy.

The coloured plate which illustrates Sir NORMAN WALKER's article vividly portrays the improvement in the nodules which followed the treatment adopted. The leprosy bacillus, as is well known, has not yet been cultivated on artificial media, so that in preparing a vaccine recourse had to be made to a triturated

Diagnosis of Congenital Heart Disease in the New-born, including a Record of Cases of Fœtal Endocarditis and Mal-development. The writers remark that it is sometimes very difficult to differentiate between such widely different clinical states as (*a*) primary heart failure; (*b*) acute broncho-pneumonia without fever in a stage so early that heart failure seems improbable; (*c*) pulmonary atelectasis, where cyanosis and rapid breathing are the chief or only signs; (*d*) cerebral hæmorrhage, where cyanosis and rapid pulse and respiration predominate; (*e*) supra-renal hæmorrhage, where the same signs are present; (*f*) diaphragmatic hernia accompanied by cyanosis and periodic dyspnœa.—Dr. G. Kerr Cross makes a Report on Blood Transfusion Work Seen in the Hospital for Sick Children, Toronto, Canada. From Oct. 1st, 1922, to Sept. 30th, 1923, 394 simple transfusions and 122 exsanguination transfusions were carried out at this hospital. The indications for simple transfusion were (1) gross hæmorrhage, (2) anæmias of all kinds, (3) shock of all kinds, (4) as a preparation for operation in debilitated patients, (5) as a therapeutic measure in cases of marked debility. The results were excellent in anæmias, hæmorrhages, and debility, and of much greater service than intravenous injections of saline or gum acacia in shock. In post-operative conditions the method was a very valuable prophylactic against shock, considerably diminishing the mortality, especially in pyloric stenosis and intussusception. It also proved useful as a pre-operative measure. The indications for exsanguination transfusion were (1) septicæmias, such as erysipelas; (2) septicæmias suspected, but not proven; (3) intoxications, including the toxic stage of burns, acute intestinal intoxication of infants, and intoxication of human or unknown origin. Excellent results were obtained in erysipelas, and in toxæmia caused by burns exsanguination transfusion appeared to offer the only hope of recovery, while in acute intestinal toxæmia the mortality was reduced by half.—Dr. G. W. Ronaldson contributes a Note on "Spasmodic" Diphtheria, with two illustrative cases, showing that diphtheria may be complicated by spasmodic nervous symptoms, which are most likely to be found in persons with a nervous predisposition. These symptoms are rare, and it is doubtful if they ever occur in patients who have not suffered from diphtheritic angina. Further proof is needed before a diphtheritic origin can be assumed for such symptoms in subjects who have no characteristic symptoms of diphtheria.—Dr. Macdonald Critchley reports a case of Post-diphtheritic "Chorea," associated with the ordinary diphtheritic polyneuritis, and alludes to a similar case recorded by Globus.—Dr. J. M. Smellie describes three cases of Congenital Duodenal Occlusion. Two died within a few days of birth, which is the almost invariable rule, and the third survived for nearly three months. The site of the occlusion in one case was just below the opening of the common bile-duct, of which type there are about 23 recorded cases. In the second case the duodeno-jejunal flexure was the site, of which type about 11 examples have been observed. In the third case the occlusion occurred just above the opening of the common bile-duct, but there was also a complete interruption in the continuity of the gut, and the second part of the duodenum appeared to arise from the junction of the common bile-duct and pancreatic duct. No previous example of this variety seems to have been reported.—Dr. F. Parkes Weber writes on Developmental Telangiectatic Hæmorrhage and So-called "Telangiectasia"—Familial and Non-familial, which includes telangiectatic epistaxis, hæmoptysis, hæmaturia, hæmatemesis, and bleeding from the rectum.—Dr. Parkes Weber also contributes a paper entitled a Law Regarding the Distribution of the Depigmented (Leucodermic) Patches of Vitiligo when they are added to Mole-like Nævi.—In a paper on Acute Appendicitis in Children: 120 Consecutive Cases, Mr. W. A. Thompson, of Liverpool, discusses the diagnosis and treatment of this condition with details of his cases in tabular form.—Dr. W. G. Wyllie records a case of Amyotonia Congenita in a girl aged 4½, who had been kept under observation for three years, during which gradual improvement had taken place.—The abstracts from current literature are devoted to acute infectious diseases.

NEW INCOME-TAX PROVISIONS.

The Finance Act, which has just come into force, contains a number of interesting provisions, the general effect of which is to lighten the burden upon the taxpayer in respect of certain classes or categories. So far as the changes concern medical men the saving will arise, not qua medical men, but as members of the taxpaying community in the following ways:—

1. The rate of tax remains at 4*s.* 6*d.* (reduced rate 2*s.* 3*d.*).

2. Inhabited house duty is wholly repealed, and this somewhat irritating impost will not again appear on the demand notes issued on the first day of each year.

3. The allowance of £45 given in respect of persons taking charge of widowers' and widows' children, or acting as housekeepers, and in respect of widowed mothers, &c., has been increased to £60. This concession is the result of some years of persistent endeavour to place the allowance on a more generous basis.

4. The allowance given to widowers or widows in respect of housekeepers may now be claimed irrespective of the handicapping condition formerly existing—viz., that there must be a child looked after by the housekeeper in respect of whom the child allowance had been given.

5. Where a taxpayer derives income from foreign possessions he now is entitled to ask for an adjustment of such income to the actual total amount of the first three years of assessment. Previously assessments could be made on the basis of that applicable to trades, professions, and vocations, without the adjustment to which the latter were entitled. This provision, therefore, merely places on the same basis the liability to tax.

6. In case it may be desired to retire to some country where taxation is less burdensome, it is fairly well known that one must cease to maintain a residence in this country. There are questions constantly arising, however, as to whether a person suffering tax may be regarded as residing or domiciled abroad, but in the past difficulties have arisen in appealing from the decision of the Board of Inland Revenue. It is now proposed, therefore, to give the taxpayer a right of appeal, on questions of domicile, ordinary residence and residence, to the Special Commissioners, from whom further appeal may be made to the High Court.

7. Repayment of income-tax is now to be made at the standard rate of tax for the year or at half that rate as the case may be. Where, however, a person proves that, by reason of the deductions to which he is entitled, he has no taxable income, repayment will be made of the whole of the tax paid or suffered by him.

8. A collector of taxes is now empowered to recover summarily amounts of tax under £50, which presumably means that more cases of arrears will appear in the limelight than in the past.

9. The recipients of dividends have often been mystified by the "explanatory" hieroglyphics preceding the net rate of payment per share on dividend warrants. This difficulty is now to be remedied, and after Nov. 30th next dividend warrants must show the gross and net amounts and the rate and amount of tax deducted.

tional to the diminution of the ratio, and are accompanied at the same time by a diminution of carbon dioxide. If the ratio is increased to, say, 18 to 1 the excess of air damps the explosion in the cylinder and the flame of the explosion does not spread throughout the cylinder with a result that unburnt petrol appears in the exhaust gas. Probably, also, if the ratio is lessened to an extreme extent petrol may appear in the exhaust gas. It is, therefore, conceivably possible, dealing only with the subject of exhaust gas, that death of an individual may be caused by (1) petrol fumes, (2) carbon monoxide (carbonic oxide), or (3) a mixture of the two conditions. The first possibility is an uncommon one owing to the rapid dilution of the vapours with the surrounding air and the relatively small percentage of petrol in the exhaust gas. Further, the running of an engine under such conditions is likely to damage seriously the working parts. In the second case it is easy to see that a comparatively small alteration in the proportions of air and petrol will lead to the production of CO in proportion to the ratio of air to petrol. According to Haldane the presence of 0·05 per cent. of CO in the atmosphere will produce distinct toxic symptoms, 0·2 per cent. will produce urgent symptoms, and 1 per cent. is usually regarded as a possible fatal mixture. As the exhaust gas may contain as much as 11·6 per cent. of CO, it is not surprising that anyone remaining in a closed garage may easily succumb to poisoning from CO.

Analysis of Exhaust Gas of a 20 h.p. Daimler Four-cylinder Engine.

Petrol consumption per 1000 revolutions in lbs.		0·181	0·191	0·197	0·217	0·250	0·293
Brake load at 43 inches radius in lbs.		25·0	27·5	29·3	29·4	29·3	27·0
Measured amounts of the exhaust gas reckoned as per cent. of the volume of dry exhaust gas ..	CO_2	10·9	12·8	13·5	10·6	9·6	6·0
	CO	Nil.	Nil.	0·7	5·0	6·25	11·6
	O	3·6	1·5	0·2	Nil.	Nil.	Nil.
	H	Nil.	Nil.	Nil.	2·1	2·65	8·7
	N	84·0	84·0	84·0	81·0	80·0	73·0
Total O as obtained by dividing N by 3·76 as per cent.		22·4	22·4	22·4	21·5	21·3	19·4
Steam as per cent. calculated		15·8	16·2	16·8	16·8	17·2	15·2

CO_2 = carbon dioxide. CO = carbon monoxide. O = oxygen. H = hydrogen. N = nitrogen.

In THE LANCET [2] references to cases of poisoning by exhaust gases have been given, and the various writers are by no means in agreement as to the cause of death. In one series of 42 cases described by Dr. G. W. Johnson in Canada, he is of opinion that petrol fumes were the cause of death and not CO, and he quotes spectroscopic examination of the blood and animal experiment in support of his statements. However, whilst not being able to exclude poisoning by petrol or by decomposition products other than CO, it seems to be impossible to exclude CO at all events as a partial factor in these cases. The examination of the blood spectroscopically in these cases for CO is of great value when a positive result is obtained, but "death may occur before the hæmoglobin becomes sufficiently charged with CO as to afford spectroscopic evidence of its presence,"[3] chiefly owing to the masking of the CO bands by oxyhæmoglobin and reduced hæmoglobin. The post-mortem appearance of the internal organs is usually characteristic, as also their resistance to putrefaction, but in some cases where death occurs rapidly, or where the patient has lived some days after exposure to CO, the post-mortem appearances are so indefinite that a certain diagnosis of CO poisoning at post-mortem becomes impossible.

In the article by Drs. Blacklock and Peacock it seems probable that the lethal effect of the exhaust gas was due to CO. It is a little unfortunate that no detailed account of the symptoms displayed by the rats is given and that no details of post-mortem examinations on the rats are available. The fact that the rats were not driven out of the drain is suggestive of CO poisoning, as, of course, this gas is odourless and tasteless and not in any way irritant. Again, when the motor-launch was used the exhaust gas was mixed with water and no impairment of the lethal effect was noticed. Under such conditions many substances, such as petrol vapour, would be removed by the water, but CO being only slightly soluble in water would be discharged in the exhaust gas unchanged. Nevertheless, it is conceivable that some decomposition product of petrol and air other than CO may be concerned, but no suggestion of any such compound is mentioned in the treatises on internal combustion engines with the exception of minute traces of aldehydes. If the effects on rats were really brought about by CO, the internal combustion engine appears to be a rather inefficient and uneconomic source of CO, if any other is available.

Annotations.

"Ne quid nimis."

MEAT INSPECTION IN SCOTLAND.

ADEQUATE supervision of meat intended for human consumption is a subject upon which public health authorities have for years concentrated much criticism, but without obtaining any advance in procedure. All recognise that present conditions in England are supremely unsatisfactory, involving great inequalities and great injustices. In some areas keen and efficient supervision is exercised, in others there is hardly any supervision. This is bad alike for the public, the meat industry, and the local authorities. In the United Kingdom, Scotland has led the way in establishing a system of uniformity of inspection and judgment. These are dealt with in the Public Health (Meat) Regulations (Scotland), 1924. Dr. Gerald Leighton has recently published a useful handbook,[1] mainly intended for meat inspectors and others officially concerned, as a guide and explanation of these regulations. The essential principles adopted are worthy of study. Two classes of inspection officer are recognised—meat inspectors and detention officers. A meat inspector is no longer to be any person who is entrusted with the duty of inspecting meat, irrespective of his competency, but one who possesses certain definite qualifications. As defined, it includes the medical officer of health of the district, or a veterinary surgeon, or a person who has received special training in the work of meat inspection, and, prior to June 1st. 1923, has had not less than seven years' practical experience in this work and has obtained from the Scottish Board of Health a certificate of qualification. The "detention officer" is an innovation, and is any person possessing certain qualifications who is appointed by the local authority for this purpose. The qualifications required are such experience and training as the meat inspector of the district may consider necessary to enable him to recognise any departure from the normal in the carcass, organs, or viscera of an animal. His duty is to detain, and neither to seize nor condemn. These powers rest with the meat inspector, who must be trained, and as Dr. Leighton remarks, the new regulation "cuts out once and for all the placing in the hands of utterly incompetent persons the important duty of inspecting meat."

nodule which had been excised. The emulsion was heated to 60° C. for half an hour and diluted with carbol saline, which was injected in the doses of 1 c.cm. weekly, containing approximately 200 million leprosy bacilli. The difficulty in assessing at its true value the effect of any particular treatment in a given case of nodular leprosy is very great. Partial resolution of the nodules has been claimed as the result of many different forms of treatment. Similar success has been recorded with chaulmoogra, with its salts, the gynocardates and hydnocarpates of soda, by Deycke with nastin—a vaccine prepared from a streptothrix grown from leprotic nodules—and with injections of antimony. Caution is necessary, for Dr. E. Muir and others have shown that at certain periods the leprotic process may become stationary and that under appropriate hygienic and dietetic conditions the disease may be ameliorated in a remarkable manner, at any rate for a time.

◆

LONDON WATER.

The eighteenth annual report[1] of the Metropolitan Water Board contains the results of the chemical and bacteriological examination of the London waters for the 12 months ended March 31st, 1924. As in previous years, Sir Alexander Houston begins by setting out how the immense task of providing nearly seven million persons with water fit to drink is carried out with such apparent ease and regularity. This year he indulges in a little legitimate boasting in view of the vast army of strangers who are visiting the British Empire Exhibition at Wembley without anxiety as to their supply of drinking water; he infers that there is no other large populated centre in the world which can afford the same amenities. The Director of Water Examination does not let his readers take for granted everything that has appeared in previous reports, and he asks this year the rhetorical question: Why is it necessary to purify water at all?—in order to set out again some of the reasons, physical, sentimental, and hygienic, which determine the answer. Although, as he says, many people have an almost invincible repugnance to the addition of any chemical to water destined to be used for drinking purposes, yet medication has now become an accepted practice, whether as lime for softening or hardening waters, alum for clarification, oxidising filters for removal of iron, permanganate for taste, copper sulphate to kill algæ, and so forth. In an interesting section he foreshadows the possible addition to London water of the modicum of iodine required to prevent the development of goitre, recalling Dr. C. N. Atlee's recent observation that 34 out of 895 unselected boys under the age of 12 in a south-eastern quarter of London had thyroid enlargement and 43 out of 944 girls, respectively 3·8 and 4·5 per cent. of children examined. The prophylactic experiment, carried out at Rochester, U.S.A., of artificially iodising the water-supply twice a year for a period of about two or three weeks, opens up a vista of possibilities of conveying to consumers in their water-supply substances of preventive or curative nature. The experiment costs Rochester only £357 a year on a daily consumption of some millions of gallons. To think of a water-supply in the light of a preventive of disease is a new and attractive idea.

Water-borne infectious disease is still a very complex question. Generally speaking, Sir Alexander Houston writes, it is very hard to associate typhoid fever causatively with water-supply in this country. Despite laborious effort, he has failed to isolate the typhoid bacillus from sewage or from impure river water before purification. Indirectly, he has arrived at the rough-and-ready rule that any volume whatever of any water-supply, which contains no more than 704 excremental bacteria, can reasonably be supposed not to harbour the typhoid bacillus in that volume; and he goes on to consider the question of the number of bacilli necessary to start an infective process. Theoretically, of course, one may suffice, but, even should typhoid bacilli be present in a water-supply, infection would not necessarily result so long as they do not occur in clumps or masses, but are so few and evenly distributed that no single draught of water can contain more than a single germ. Unfortunately, however, waters showing no gross signs of bacterial pollution, as judged by ordinary standards, have been the means of causing widespread disease. There is only one safe course to adopt—namely, to regard as anathema all adventitious water entering a supply during and after purification. Once having entered the custody of a water-works authority, water should be regarded as sacred until it has reached the consumer in a condition of proven safety. An unexpected attack on London water has recently been made by the sea-gull, which seems to be changing its habits and to be finding land waters more attractive than the seashore. Photographs reproduced in the report show a hundred or more gulls flying over a single filter, and although, so far as is known, gulls do not suffer from the water-borne diseases which afflict human beings, their droppings produce an excremental pollution which cannot at present be differentiated from contamination of human origin. The Board's engineering department has recently organised a system of frightening away the birds by frequent firing of blank cartridges, but apparently the sea-gull must be reckoned with as a permanent invader of the solitude of reservoirs which have hitherto been the nesting-ground of such comparatively rare birds as the great crested grebe. The report is both learned and entertaining, and contains matters with which every citizen of Greater London should be familiar. In octavo form at a third the price it might obtain the readers it deserves, though we can see that the production was costly.

◆

TOXIC EFFECTS OF EXHAUST GAS.

In the current number of The Lancet is a paper by Dr. D. B. Blacklock and Dr. W. H. Peacock on the destruction of wild rats by means of the exhaust gas of the petrol engine. In the *Times* of July 9th, 1924, a verdict of death by misadventure was recorded by a coroner on a man who was found dead on the floor of a garage close to the exhaust outlet of a motor-car. The engine was running. The composition of exhaust gas of internal combustion engines is therefore important, and the analysis made by Hopkinson and Morse at Cambridge given in the table, shows that the efficiency of the engine as indicated by the brake load did not vary very much with the varying amounts of petrol used. The analysis of the exhaust gas varied considerably. According to Judge[1] the mixture which gives the nearest resemblance to perfect combustion—i.e., complete oxidation of all the carbon and hydrogen of the petrol—is 14·75 parts of air to 1 part of petrol, and even then traces of carbon monoxide are formed. Such proportions probably occurred under the conditions given in column 2 of the table. If the ratio is lessened to, say, 12 or 10 parts of air to 1 of petrol, combustion is incomplete and CO and H make their appearance in quantities proporbouring sculptures representing women, suggests to the anatomist that the human figure has vastly changed since her remote epoch, but the sculptured men on either side of her at once belie this supposition, for they are tall, symmetrical, despite the rudeness of their representation, and one at least is surmounted with a finely developed skull. It is conceivable that the men represented in the Laussel sculpture were invaders who, like the earliest Saxon and Danish invaders in England, brought none of their womenkind with them and were compelled to fight each other for the cave-women of Neanderthal type.

AIR EMBOLISM IN OBSTETRICS.

IN a paper read before the Chicago Gynecological Society, Dr. James A. Gough,[1] who reports an illustrative case, remarks that the significance of air embolism in obstetrics was first recognised in 1829 by Legallois, who suggested that the entrance of air into the uterine veins might be a source of danger in recently delivered women. Since then many cases have been reported, but the extreme infrequency of the condition is shown by the fact that Opitz never had a case among 4500 deliveries. As many of the recorded cases of supposed gas embolism were published before the dawn of the bacteriological era, it is reasonable to suppose that a certain proportion of them were of microbic origin. Welch and Flexner in 1896 studied several cases in which the presence of gas at the autopsy had been considered evidence of air embolism, but which they demonstrated were due to the agency of gas-producing organisms. Dr. Gough's case was that of a II.-para, aged 25, in whom episiotomy was performed under light ether anæsthesia. Collapse took place immediately after the operation, and death occurred seven hours after delivery, respiratory failure and deep cyanosis preceding cessation of the heart's action. The necropsy, which was made nine hours after death, showed that the right ventricle was markedly dilated and had flabby walls which appeared transparent. When opened under water the right ventricle was found to contain much free air, and frothy blood also escaped from it. Frothy blood was also found in the pulmonary artery, but the blood elsewhere did not contain air, and there were no signs of post-mortem decomposition. On histological examination there was no evidence of gas bacillus infection, and examination of the blood showed no bacteria. The case therefore appeared to be a genuine example of air embolism following delivery.

MEDICAL INCUNABULA.

EARLY printed books have evoked greater interest of late years among collectors of historic medical literature than at any previous period. In a recent sale at Messrs. Sotheby's as many as 50 early printed works on medicine and surgery were put up to auction, and some of these will doubtless soon reappear on the shelves of the booksellers. In Catalogue 22, issued by the International Antiquariaat of Amsterdam (Menno Hertzberger), we find nine incunabula offered for sale, to each of which an interesting bibliographical history attaches. Conspicuous among these nine is the Celsus published by Pachol and Scinzenzeler at Milan in 1481. This, the second edition, is considerably rarer than the first. The book was apparently not seen by Hain or Proctor, those indefatigable bibliographers, but was known in 1764 to De Bure, who speaks of it as "encore rare et recherchée des curieux" in his "Bibliographie Instructive." He catalogues also at great length the first edition of Celsus, pointing out that his predecessors have been in the habit of dating it 1475 instead of 1478, owing to their not having looked closely enough at the curiously printed year of publication in the colophon or end-title. De Bure, one of a family of Paris booksellers who became famous for their catalogues of the libraries of a learned period, claims to have put on record the greater part of the books issued in the republic of letters since the invention of printing, but he only mentions some 14 medical incunabula. And this proves that bibliography, and, by inference, collecting had not progressed far in his day. Ideas as to value are relative. He, for instance, considers the first edition of Celsus to be *fort rare*. The present age, with its far larger outlook on the republic of letters, has decided in favour of the second. The beautiful, tall, clean, and unwashed copy, now on sale at the International Antiquariaat, is offered for 450 guilders.

In the same catalogue among the nine medical incunabula we note Hartmann Schedels's "Liber Chronicarum," printed at Nuremburg by Anth. Koberger in 1493. It is a folio with clasps, and besides being considered the crown of mediæval craftsmanship in bookbinding, is illustrated with more than 1800 fine woodcuts by the teachers of Dürer—namely, Wohlgemut and Pleydenwurff. A number of famous medical authors from Alexander to Trusianus are mentioned in its pages, and there are references to the finding of the body of a giant, to *lues* on a great scale, to a monster in Gascony, to the names of known human monsters, to a chicken with four legs in France, and to the Seven Sleepers of Christendom. This fine copy with large margins is in the original calf binding with clasps, and contains the three blank pages and the discourse on Sarmatia usually missing. The price is 650 guilders. Book illustrations of the Dürer school are always admirable, and when the subject is medical, as when baths, hospitals, operations, and anatomy lessons are depicted, they are often of great historic value. Some of the best ancient medical woodcuts adorn title-pages, and would appear to have a mystical significance. In these title-pages vignettes illustrative of medical life are often to be found, and deserve detailed study. A catalogue of more than 150 such title-pages has been prepared at the library of the Royal College of Surgeons of England.

ADRENALIN AS AN ANALGESIC.

IN a comprehensive, even discursive, article[1] Dr. D. Paulian, of Bucharest, discusses the action of anæsthetics in general, and of adrenalin in particular. Such drugs as antipyrin, salicylates, and morphine, on the evolution of a common cold he suggests act like sleep, reducing the phenomena of inflammation, for the time being at any rate, by diminishing the conductivity of the sensory nerves. It has been argued that salicylates are effective in certain diseases, mainly because they block impulses which, in their absence, would travel by the sensory nerves to the central nervous system. Indeed, it has been shown that aspirin and atophan are antifebrile simply because they reduce the excitability of the central nervous system. At Prof. Marinesco's hospital in Bucharest Dr. Paulian has been investigating the action of adrenalin on the gastric crises of tabes. Of its ability to mitigate these crises and relieve the lightning pains of tabes there could be no doubt; of its mode of action it was difficult to be certain, but Dr. Paulian considers as plausible the hypothesis that the favourable effect of adrenalin depends in such cases on a rise of blood pressure. He has found that in all cases of tabes associated with disease of the aorta the arterial pressure is below normal, and this hypotension is exaggerated during gastric crises and attacks of lightning pain. He has noticed that the relief obtained by an injection of adrenalin during a gastric crisis is accompanied by an appreciable rise of the blood pressure, and he is inclined to think that the best explanation of the asthenia of tabes is to be sought in its concomitant hypotension. Whatever the explanation, it seems clear that adrenalin is a rapid and effective remedy for gastric crises, and though it is most potent when given by subcutaneous injection, it is not absolutely inert when given by the mouth. One of Dr. Paulian's

[1] Paris Médical, August 9th, 1924.

As regards public abattoirs detailed records have to be kept; the actual form of record is not specified, but they must be such as are approved by the central authority. Private slaughter-houses have to be licensed every year. The control over killing in these private slaughter-houses is effected by granting the licence with conditions that slaughtering shall only be carried out on specified days and at specified hours. This condition has frequently been stressed by medical officers of health as the only practicable way to supervise meat in private slaughter-houses. Killing at other times is only permissible on giving special notice, with a clause excluding from the condition immediate slaughter necessitated by accident or illness. The dangerous possibilities of this concession dealing with emergency slaughter are guarded against by regulations requiring prompt notice to be given to the clerk of the local authority and by making it the duty of the meat inspector or detention officer to inspect within 24 hours. The owner has to preserve the carcass and organs undetached for this period if necessary. The rather vexed question of meat stamping is also dealt with and a compromise is effected; stamping is not made compulsory, but local authorities are authorised to stamp meat, subject to the approval of the Scottish Board of Health.

The control over the preparation, storage, and sale of made meat products, such as brawn, sausages, and the like, is, perhaps, outside the scope of the regulations, but is not entirely neglected. These foods are included in the definition of "meat food product," and one regulation requires that meat or meat food products must not be stored in any premises that are not kept in a clean and sanitary condition. The regulations do not appear, however, to include any conditions governing the preparation and supervision over these meat food products. At present such regulations are badly needed. Another regulation of interest is one which requires that every local authority shall keep a register of all cold stores within their district, the register to include the recording of a number of essential details. The extremely important subject of uniformity of inspection and of the pathological conditions which justify seizure is dealt with by setting out such conditions in detail in the first schedule. Dr. Leighton remarks that it occupies only about five pages of print, but that "in those five pages is included the whole duty of an inspector of meat." It is evident that these directions have been compiled with great care and by men of practical experience. As an illustration the conditions which justify seizure of the whole animal, or only specified parts, in cases of tuberculosis are set out with great clearness.

No one can study the regulations without appreciation of the thorough way in which the subject has been investigated, with careful anticipation of practical difficulties. Dr. Leighton has added to the debt by his succinct discussion of the meaning and objects of the regulations which constitute a public health reform of great value. He points out that an important factor in their initiation and practicability is the fact that over 90 per cent. of the total consumption of home-killed meat in Scotland is dealt with in public abattoirs. There seem no insuperable reasons why similar regulations should not be adopted in England, but it would appear that the scientific administrative procedure could not be initiated without new legislation. For example, that hoary anachronism, the "registered" slaughter-house, usually including the worst slaughter-houses in the area, stands on the authority of an Act of Parliament. The simple solution of allowing slaughtering only at prescribed times as a condition of licensing cannot prevail for these slaughter-houses since no licensing is required. Most of the bad meat trade centres in the rural areas and it is in these that powers to regulate are so deficient. It is of limited value to adopt a uniform standard of judgment for meat unless also a better administrative machine is evolved for English conditions. The Scottish machinery provides an admirable example.

THE PROGRESS OF MAN.

ANOTHER volume in a series of little books entitled "Today and Tomorrow" has appeared in sequence to Mr. J. B. S. Haldane's "Dædalus" and Mr. Bertrand Russell's "Icarus," the former of which purported to expose the promises of science, especially of biography, while the latter dwelt upon the sinister possibilities which accompany scientific developments, threatening to make of man's new wisdom an engine destructive to man. "Tantalus"[1] is intended to provide an antidote to much learned pessimism, but Dr. Schiller starts gloomily enough with the premise that man has always in the course of his ascertained history been placed in the dilemma that as fast as his ingenuity might bring him nearer happiness his failings perverted the knowledge before his virtues allowed him to employ it rightly. The happier message of "Tantalus" is that, given time in which its effects can work, we have in the science of eugenics an escape from the impasse. And the leaders of this science must accustom themselves, we gather, to look steadily backwards as well as forwards, man having ceased, biologically speaking, to be a progressive species. The argument here relies on the magnificent physique of the Cro-Magnon people of the Aurignacian Age, and as to this we have remarkable contemporary evidence. Truth in the sense of accurate portrayal of what is observed by eye was well known to primitive man, whose sense of beauty was, however, not ours. But their sense of truth was as keen as our own. This is apparent to all those who have examined prehistoric sculpture and cave-painting in the Abri de Laussel in Dordogne or in the caves of Spain. Early man was an accurate reproducer of what we should consider to-day execrable human models, but there is a probability that he admired what he reproduced.

The cave of Laussel was first examined in 1908 by M. Gaston Lalanne, who described his discoveries in *L'Anthropologie* in 1912, with reproductions of the rude sculptures of the Upper Aurignacian epoch of from 25,000 to 40,000 years before the advent of historic civilisation. These sculptures chiefly represent nude female figures of the steatopygous type found among lowly African races. Every feature of the female figure is here depraved to modern civilised thinking. The breasts are enormous and pendant, the hips extraordinarily wide, the abdomen superficially vast, the whole figure stunted. In strange contrast to these almost infra-human types there was found on one wall the figure of a tall and well-formed man. Lalanne was of opinion that the man was an archer in the act of drawing a bow, but certain details in the bas-relief have lately led to different conclusions. These are well set out by Prof. Dr. P. Shiefferdecker, of Bonn, in an article entitled "Ueber ein Bildwerk aus der Urzeit," contributed by him to Vol. II. of the "Libro en Honor de D. S. Ramón y Cajal," published by the admirers of the famous Spanish surgeon and man of science. Taking the figure of the supposed archer as his theme, Schiefferdecker shows that this tall man is one of a group of three who are engaged in the kind of contention of which the prime example in history is the Rape of the Sabines. There are two tall men, and they are fighting at the mouth of a small cave for the possession of one small woman; the archer is curving his arm round her diminutive figure, protecting or withdrawing her from the other man. The men are manifestly beings of a larger race than the woman, and it is conjectured that they are specimens of that gigantic Cro-Magnon race, which in brain-capacity and stature so surpassed any subsequent Europeans. The crouching, cowering woman, on the other hand, is conjectured to be a surviving Neanderthalian, one of that ape-like tribe that possessed Europe prior to the arrival on the ethnologic scene of the Cro-Magnons. These races are believed to have overlapped, and both to have disappeared as a whole, but to have left traces in our physical make-up. The female figure, taken in conjunction with neighdiameter of the pencil of X rays. These leave in the direction of the axis through the glass window (1) in the base of the tube. An unevenness of the tungsten spiral thus has no unfavourable effect, while the luminous wire is so thin as scarcely to intercept any rays from the anticathode, and no shadow from the wire is cast on the plate. The three insulating layers of the cylinder are shown: chrome iron (9), lead (10), copper (11), while (8) is a glass tube which isolates the anticathode from the cathode. Cooling takes place by filling the space (13) with water. Experiments have been made with tubes of similar type for deep therapy and are likely soon to be placed on the market. It is clear to us that this Dutch tube presents features not possessed by other tubes. It contains its own device for protecting the operator from extraneous rays, the wall of the tube is practically impervious to the rays, and only those which are used pass out. The shape of the tube allows readier approximation to the body, especially in the less accessible regions, while the earthing of the cathode renders it safe for the patient or operator to touch the tube without risk when it is being worked. Radiologists would certainly do well to examine this tube for themselves.

[1] Tantalus. By F. C. S. Schiller, M.A., D.Sc. 1924. Kegan Paul. Pp. 72. 2s. 6d.

AN EASTERN CLAN.

THE Palaungs are a tribe living in the district of Tawnpeng, which lies in the Shan States about longitude 97° E. and around the twenty-third parallel of N. lat. They are a little-known race and untouched by Western ideas, and as Mrs. Leslie Milne says in the introduction to her book entitled "The Home of an Eastern Clan: A Study of the Palaungs of the Shan States"[1]: "The East is changing so rapidly . . . that the customs of a people off the beaten track and as yet uninfluenced by contact with the West, are, I think, worth preserving." A vast amount of information about their psychology, religion, and social customs has been collected and arranged by Mrs. Milne. Her first task was naturally to learn the language, and she gives an amusing account of her difficulties. For instance, she had collected the Palaung words for "walk" and "run," "sit" and "stand," but not for "jump." So she jumped over a stick on the floor, and then down off a box. All the Palaungs present shouted "ru," which word she put down in her note-book as meaning "jump." But when she revised her notes with an interpreter she discovered that "ru" really meant "mad." Chapter XII. is devoted to medicine, charms, and omens. The religion of the Palaungs is Buddhist, but tinctured with much survival of spirit worship, and nearly all the ills of life are considered as due to evil spirits. Hence, treatment is mainly a matter of propitiating the evil spirit in question, though, in addition, sundry medicinal plants or animals, and minerals such as lime or wood ashes—i.e., potash—are used. The chapter on spirit worship is particularly interesting, and together with the portion of the book dealing with folk tales is one more proof of how popular beliefs are the same all over the world. On p. 352 is a story of possession by a "pok," which is a spirit living in a graveyard. Can it be that this name is the same as "Puck" or the Welsh name for a fairy—i.e., "pwci"? The story is that of an old woman who died, and after her death her children dressed her body in the habit of a Buddhist nun. Next day, while she lay in her coffin, knockings were heard, and the bystanders on opening the coffin found her apparently alive. She was helped out, set by the fire and given food, which she ate voraciously. She could not speak but only made strange sounds. A year passed and then a monk came to the relatives saying that the revived body was not really their mother, but only the dead body animated by a "pok." He gave them certain directions and on these being carried out the "pok" fled away, leaving only a loathsome corpse apparently dead a year. Let the reader compare this tale with that masterpiece of Stevenson, "Thrawn Janet," and note the curious resemblances. Both bodies after death animated by an evil spirit; both of them unable to speak intelligibly, and both freed from the spirit by the ministrations of a minister of religion. Not anthropologists alone, but all who are interested in the Empire to which they belong ought to be grateful to Mrs. Milne for this book.

BISMUTH IN EXPERIMENTAL SYPHILIS.

Ehrlich's successor, Prof. W. Kolle, has published an account[1] of the prophylactic use of arsenical preparations, mercury and bismuth, in experimental syphilis, and his observations in the case of the last-named drug are instructive. He anticipated that bismuth would not be more effective than mercury in rendering experimental animals resistant to infection, but to his surprise he found that mercury had only a transitory effect in this respect. When, however, he injected insoluble salts of bismuth which were retained in the body as depôts at the site of injection, it proved impossible to inoculate with syphilis successfully. In the case of 26 rabbits given an intramuscular injection of bismuth, followed by intra-testicular inoculations of spirochætes from two to fifteen weeks later, there was not a single instance of a chancre developing. X ray examinations showed that these insoluble salts of bismuth, including the carbonate which is quite insoluble in water, could remain for months embedded in the muscles into which they had been injected. Control tests carried out with 68 animals which had not been given preliminary treatment with bismuth showed that 94 per cent. of them developed a chancre at the site of inoculation. In another series of controls, where the animals had been treated with easily absorbed preparations of bismuth, refractoriness to infection was in most cases short-lived. The upshot of these observations would seem to be that a single bismuth "stopping" left in the body is capable of rendering it refractory to infection with syphilis for as long as four months. Prof. Kolle sounds a warning with regard to drawing hasty conclusions as to the applicability of his observations to man. It must first be shown that the bismuth-treated rabbits did not contract experimental syphilis in some latent guise which dispensed with a chancre at the site of inoculation. For, as in the case of prophylactic treatment with arsenical preparations, it is conceivable that resistance to infection may be acquired only up to a degree which does not exclude the development of an abortive form of syphilis. It is also, as Prof. Kolle points out, desirable that his experiments on rabbits should be repeated on monkeys, and that they should react in the same way before general conclusions are drawn as to the prophylactic value of bismuth. If man reacts like the rabbit in this matter to bismuth, it is obvious that a very important advance has been made toward the prophylaxis of syphilis in man.

WE regret to record the death at Bournemouth, on Sept. 6th, of Sir Frederick Needham, Commissioner of the Board of Control, aged 88 years.

THE death occurred on Sept. 9th of Dr. Robert James Farman, secretary of the Panel and Local Medical Committees of the County of London.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The distribution of prizes to the students will take place in the out-patients' hall of the hospital on Oct. 1st, at 3.30 P.M., by Sir Humphry Rolleston. Dr. W. Cecil Bosanquet, senior physician to the hospital, will be in the chair.

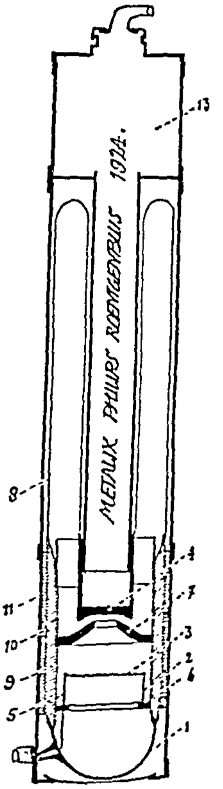
DIPLOMA IN PUBLIC HEALTH.—A course of lectures and demonstrations under the Metropolitan Asylums Board, dealing with hospital administration, will be given at the North-Western Hospital, Lawn-road, Hampstead, N.W., by Dr. E. W. Goodall on Mondays and Thursdays at 4.30 P.M. and alternate Saturdays at 10.30 A.M., beginning Thursday, Oct. 2nd, for a period of three months.

patients was an army officer who used to be aroused at 5 o'clock every morning by an irresistible desire to go to stool. He was able to abort these attacks as soon as they began by swallowing 10 drops of adrenalin. In neuralgia of the sciatic nerve and in rheumatic affections of the joints adrenalin has been found remarkably efficacious, even when the rheumatism has been complicated by effusions into joints. It may be that adrenalin is beneficial in tabes because the action of the suprarenals is defective; such an hypothesis would explain the general weakness and many of the other symptoms of tabes. Whatever the mechanism of adrenalin artificially introduced into the body may be, there can be no doubt as to the analgesia and euphoria which it creates, and in this respect it assuredly deserves more attention than it has hitherto received from physiologists and physicians.

PREGNANCY AND PULMONARY TUBERCULOSIS.

AT the fourth meeting of the International Union against Tuberculosis held in July at Lausanne, interesting discussions centred around a paper read by Prof. Calmette on the possibility of virulent tubercle bacilli being evolved from avirulent germs, a paper by Prof. Sahli on the defences of the organism against the tubercle bacillus, a paper by Prof. H. Forssner on the relation of pregnancy to tuberculosis, a paper by Prof. L. Bernard on the prevention of tuberculosis in infancy, and a paper by Sir Robert Philip on the decline in the tuberculosis mortality resulting from the organisation of tuberculosis campaigns in different countries. The International Union against Tuberculosis has its headquarters in Paris at the office of the League of Red Cross Societies, which also houses the secretariat of two other international societies combating venereal disease and cancer respectively. It would be difficult to over-estimate the importance of this centralisation of international movements against three of the principal groups of diseases, the inter-relations of which deserve the closest study. The paper by Prof. Forssner on the alleged influence of pregnancy on tuberculosis drew comments, mostly favourable, from many of his audience, and this was the more remarkable as his conclusions would have been generally regarded as hopelessly unorthodox only a few years ago. His thesis that "a pregnancy continuing till term is no more dangerous for first-stage tuberculous women than for healthy women, and by not interrupting this pregnancy we obtain for the race healthy children, just as viable as other children," was supported by much carefully sifted evidence. His material consisted of women treated in the tuberculosis dispensaries of Stockholm and, in a certain proportion of cases, recently confined in maternity hospitals. The Swedish National League against Tuberculosis financed for six years a systematic examination of all the women confined in two maternity hospitals in Stockholm. Of more than 30,000 women thus examined, 1500 were kept under observation on account of the diagnosis or suspicion of tuberculosis, and 341 women who suffered from pulmonary tuberculosis, and who were kept under medical supervision for more than a year after confinement (usually for two years or more), were compared with 396 women whose pulmonary tuberculosis was not complicated by pregnancy. After a two years' observation period, the non-pregnant women in Turban's first stage were compared with the women who had been pregnant and had also been in the first stage of the disease. It was found that the disease was stationary or the patients had improved in 59 per cent. of the first class, and in 60 per cent. of the second class. Only a slight difference in favour of the non-pregnant patients could be found in those whose disease was in the second and third stages. As for the influence of the mother's tuberculosis on the health of her child at birth, it was found that the average weight of the infants of sputum-positive mothers was equal to that of the infants of healthy mothers. There can be little doubt that Prof. Forssner's paper and the confirmation which his views received in Lausanne last month will do much to check the practice, fairly common in some countries, of inducing abortion in the subjects of pulmonary tuberculosis on the assumption that (1) the prospective mother's health will benefit, and (2) the value of her progeny will prove negligible. Prof. Forssner's paper will shortly appear in the *Bulletin* of the International Union.

A NEW X RAY TUBE.



OUR Dutch correspondent sends us an account of an X ray tube recently placed upon the market by the firm of Philips, in Eindhoven, and called by them "Metalix." One of the first trial tubes was recently seen in action by the visiting tuberculosis specialists at Dr. Bronkhorst's sanatorium in Apeldoorn, and the tube was demonstrated at the factory to foreign medical officers of health, who expressed surprise at its appearance. The new tube consists of a cylinder 40 cm. long and 6 cm. in diameter which, through regulation of the current, can be made to give larger or smaller doses of hard or soft rays. These leave the tube in one direction only, through a window in the base. The lining of the tube consists of three layers—chrome iron, lead, and copper—of such thickness that less than one-millionth part of the total energy passes out to be lost or to harm the operator. The space within which the discharge takes place is lined entirely by metal which forms part of the cathode and can be earthed, so that the patient can touch the tube without danger, provided that the transformer is also earthed. The tube can thus be brought without hesitation close up to the object to be X rayed, and as it gives a sharp and fine picture a relatively small current can be used. At present two kinds of tube have been placed on the market: Metalix A, for odontological use, with a maximum voltage of 50,000 and 9 cm. spark-gap, the maximum continuous charge being 5 milliamps, or 15 milliamps for 20 seconds; Metalix B, for radiography and radioscopy, with a maximum voltage of 65,000 and 13 cm. spark-gap, the maximum continuous charge being 8 milliamps or 50 milliamps during a short time. The price of these tubes is stated not to be higher than that of the ordinary Coolidge tube. In the sectional plan the luminous wire (3) is seen stretched between two poles, one of which (2) is in contact with the metallic lining of the tube, and thus can be earthed, the other (5) being insulated. From the luminous wire electrons are sent out into the space bounded by the metallic plates (6) and (7) and by the lining of the tube. Plate (7) contains an opening of such shape and size that the positive field of the anticathode behind it is sufficient to throw electrons from the cathode on the tungsten spiral (4) at a speed determined by the difference of tension existing between the cathode and anticathode. The size of the opening in plate (7) determines at the same time the diameter of the pencil of X rays. These leave in the direction of the axis through the glass window (1) in the base of the tube. An unevenness of the tungsten spiral thus has no unfavourable effect, while the luminous wire is so thin as scarcely to intercept any rays from the anticathode, and no shadow from the wire is cast on the plate. The three insulating layers of the cylinder are shown: chrome iron (9), lead (10), copper (11), while (8) is a glass tube which isolates the anticathode from the cathode. Cooling takes place by filling the space (13) with water. Experiments have been made with tubes of similar type for deep therapy and are likely soon to be placed on the market. It is clear to us that this Dutch tube presents features not possessed by other tubes. It contains its own device for protecting the operator from extraneous rays, the wall of the tube is practically impervious to the rays, and only those which are used pass out. The shape of the tube allows readier approximation to the body, especially in the less accessible regions, while the earthing of the cathode renders it safe for the patient or operator to touch the tube without risk when it is being worked. Radiologists would certainly do well to examine this tube for themselves.

AN EASTERN CLAN.

THE Palaungs are a tribe living in the district of Tawnpeng, which lies in the Shan States about longitude 97° E. and around the twenty-third parallel of N. lat. They are a little-known race and untouched by Western ideas, and as Mrs. Leslie Milne says in the introduction to her book entitled "The Home of an Eastern Clan: A Study of the Palaungs of the Shan States"[1]: "The East is changing so rapidly . . . . that the customs of a people off the beaten track and as yet uninfluenced by contact with the West, are, I think, worth preserving." A vast amount of information about their psychology, religion, and social customs has been collected and arranged by Mrs. Milne. Her first task was naturally to learn the language, and she gives an amusing account of her difficulties. For instance, she had collected the Palaung words for "walk" and "run," "sit" and "stand," but not for "jump." So she jumped over a stick on the floor, and then down off a box. All the Palaungs present shouted "ru," which word she put down in her note-book as meaning "jump." But when she revised her notes with an interpreter she discovered that "ru" really meant "mad." Chapter XII. is devoted to medicine, charms, and omens. The religion of the Palaungs is Buddhist, but tinctured with much survival of spirit worship, and nearly all the ills of life are considered as due to evil spirits. Hence, treatment is mainly a matter of propitiating the evil spirit in question, though, in addition, sundry medicinal plants or animals, and minerals such as lime or wood ashes—i.e., potash—are used. The chapter on spirit worship is particularly interesting, and together with the portion of the book dealing with folk tales is one more proof of how popular beliefs are the same all over the world. On p. 352 is a story of possession by a "pok," which is a spirit living in a graveyard. Can it be that this name is the same as "Puck" or the Welsh name for a fairy—i.e., "pwci"? The story is that of an old woman who died, and after her death her children dressed her body in the habit of a Buddhist nun. Next day, while she lay in her coffin, knockings were heard, and the bystanders on opening the coffin found her apparently alive. She was helped out, set by the fire and given food, which she ate voraciously. She could not speak but only made strange sounds. A year passed and then a monk came to the relatives saying that the revived body was not really their mother, but only the dead body animated by a "pok." He gave them certain directions and on these being carried out the "pok" fled away, leaving only a loathsome corpse apparently dead a year. Let the reader compare this tale with that masterpiece of Stevenson, "Thrawn Janet," and note the curious resemblances. Both bodies after death animated by an evil spirit; both of them unable to speak intelligibly, and both freed from the spirit by the ministrations of a minister of religion. Not anthropologists alone, but all who are interested in the Empire to which they belong ought to be grateful to Mrs. Milne for this book.

BISMUTH IN EXPERIMENTAL SYPHILIS.

Ehrlich's successor, Prof. W. Kolle, has published an account[1] of the prophylactic use of arsenical preparations, mercury and bismuth, in experimental syphilis, and his observations in the case of the last-named drug are instructive. He anticipated that bismuth would not be more effective than mercury in rendering experimental animals resistant to infection, but to his surprise he found that mercury had only a transitory effect in this respect. When, however, he injected insoluble salts of bismuth which were retained in the body as depôts at the site of injection, it proved impossible to inoculate with syphilis successfully. In the case of 26 rabbits given an intramuscular injection of bismuth, followed by intra-testicular inoculations of spirochætes from two to fifteen weeks later, there was not a single instance of a chancre developing. X ray examinations showed that these insoluble salts of bismuth, including the carbonate which is quite insoluble in water, could remain for months embedded in the muscles into which they had been injected. Control tests carried out with 68 animals which had not been given preliminary treatment with bismuth showed that 94 per cent. of them developed a chancre at the site of inoculation. In another series of controls, where the animals had been treated with easily absorbed preparations of bismuth, refractoriness to infection was in most cases short-lived. The upshot of these observations would seem to be that a single bismuth "stopping" left in the body is capable of rendering it refractory to infection with syphilis for as long as four months. Prof. Kolle sounds a warning with regard to drawing hasty conclusions as to the applicability of his observations to man. It must first be shown that the bismuth-treated rabbits did not contract experimental syphilis in some latent guise which dispensed with a chancre at the site of inoculation. For, as in the case of prophylactic treatment with arsenical preparations, it is conceivable that resistance to infection may be acquired only up to a degree which does not exclude the development of an abortive form of syphilis. It is also, as Prof. Kolle points out, desirable that his experiments on rabbits should be repeated on monkeys, and that they should react in the same way before general conclusions are drawn as to the prophylactic value of bismuth. If man reacts like the rabbit in this matter to bismuth, it is obvious that a very important advance has been made toward the prophylaxis of syphilis in man.

WE regret to record the death at Bournemouth, on Sept. 6th, of Sir Frederick Needham, Commissioner of the Board of Control, aged 88 years.

THE death occurred on Sept. 9th of Dr. Robert James Farman, secretary of the Panel and Local Medical Committees of the County of London.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The distribution of prizes to the students will take place in the out-patients' hall of the hospital on Oct. 1st, at 3.30 P.M., by Sir Humphry Rolleston. Dr. W. Cecil Bosanquet, senior physician to the hospital, will be in the chair.

DIPLOMA IN PUBLIC HEALTH.—A course of lectures and demonstrations under the Metropolitan Asylums Board, dealing with hospital administration, will be given at the North-Western Hospital, Lawn-road, Hampstead, N.W., by Dr. E. W. Goodall on Mondays and Thursdays at 4.30 P.M. and alternate Saturdays at 10.30 A.M., beginning Thursday, Oct. 2nd, for a period of three months.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. M. Hayes to *Vivid*, for R.N. Barracks, and for specialist duties.

Surg. Lt.-Comdrs.: L. F. Strugnell, R. J. Inman, A. C. Anderson, R. P. Ninnis, J. D. Murphy, H. F. Stephen, G. E. Heath, and E. B. Kelley to *President*, addl., for five months' course of instruction; A. G. McKee to *President*, for course; S. R. Johnston to R.N. Sick Quarters, Dartmouth; and F. L. H. MacDowel to R.N. Hospl., Great Yarmouth.

Surg. Lt.-Comdr. (D.): R. R. Adams to *Pembroke*, temp., for R.N. Barracks.

Surg. Lts. (D.): H. J. Luck to *Victory*, for R.N. Barracks, temp., supy. (on *Warspite*, paying off).

T. J. Prendergast and C. Joiner to be Surg.-Lts., and apptd. to R.N. Hospl., Haslar, for course.

Temp. commission of Surg. Lt. C. Cotter terminated at own request.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. L. Cotterill, on attaining the age for compulsory retirement, is placed on ret. pay.

Maj. R. Storrs to be Lt.-Col., vice Lt.-Col. L. Cotterill, to ret. pay.

Maj. H. G. Monteith is restd. to the estabt.

Capt. J. G. Gill is granted the temp. rank of Maj. whilst empld. as Dep. Asst. Dir. of Hygiene and Pathology, N. Ireland Dist.

Lt. K. Fletcher-Barrett is restd. to the estabt.

MILITIA.

Maj. D. M. Lyon relinquishes his commn. and retains the rank of Maj.

TERRITORIAL ARMY.

Maj. E. H. Marshall resigns his commn. and is granted the rank of Lt.-Col. with permission to wear the prescribed uniform.

Glasgow University Contgt. (Medical Unit), Sen. Div.: Lt. D. M. Harper to be Capt.

ROYAL AIR FORCE.

Flight Lt. W. E. Hodgins (Capt., R.A.M.C.) is granted a permanent commission in the rank stated.

INDIAN MEDICAL SERVICE.

Maj. T. L. Bomford has been appointed Civil Surgeon of Howrah, vice Lt.-Col. D. P. Goil on leave. Lt.-Col. W. T. Furloyson, Inspector-General of Prisons, has been nominated a member of the Bombay Medical Council, vice Lt.-Col. W. Gillity resigned. Maj. C. C. Kelly acts as Civil Surgeon Panch Mahals, on the return from leave of Lt.-Col. E. F. G. Tucker; Lt.-Col. R. M. Carter acts as Presidency Surgeon, Second District, Bombay, with attached duties; and Maj. S. S. Vazifdar continues to act as Second Physician and Registrar, J.J. Hospital, and Professor of Materia Medica and Pharmacy, Grant Medical College, Bombay. Capt. J. M. Shah has been appointed Personal Assistant to the Surgeon-General with the Government of Bombay.

The King has approved the relinquishment of his temporary commission by Lieut. Sengara Pillai Ponniah, on account of ill-health, and is permitted to retain the rank of Lieut.

The King has approved the retirement of the following officers: Senior Assistant Surgeons with rank of Major: W. R. D'Sylva, R. A. Bœrmel, and J. F. Gibson.

DEATHS IN THE SERVICES.

The death is announced on Sept. 2nd at Aberdeen of Surg. Lt.-Col. John Murray, M.B., C.M. Aberd., J.P., Army Medical Staff, retired, in his eighty-second year. He was born on April 6th, 1843; qualifying in 1864 he became assistant surgeon Sept. 30th, 1864; surgeon March 1st, 1873; surgeon-major Sept. 30th, 1876; and retired with hon. rank (Hon. Brig.-Surg.) Dec. 10th, 1884. He resided in London at 12, Ashburn-gardens, S.W. His name was included in the Army List of Non-effective Officers in the war years.

The death occurred on Sept. 4th at Cheltenham, at the age of 91, of Surg.-Gen. Alexander Dudgeon Gulland, who qualified M.D. Edin. 1857, and L.R.C.S. Edin. 1854. He served at the siege of Sebastopol and the expedition to Kertch, in China in 1860, and in the Hazara campaign 1868. He was a friend of General C. G. Gordon ("Chinese Gordon," or "Gordon Pasha" of Khartoum).

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXVII.—TREATMENT OF RHEUMATISM OF CHILDHOOD.

Modes of Onset.

The recognition of rheumatism in childhood at its very earliest stage is of such paramount importance in influencing treatment that a word must be said about the modes of onset of this extremely common and destructive disease. These may conveniently be divided into three groups: (1) Onset with acute symptoms; (2) onset with chorea; (3) insidious onset.

1. *Acute onset* is that familiar to those working in the medical wards of general hospitals. It usually takes the form of an acute febrile polyarthritis, which yields rapidly to treatment, but which is often followed by a varying degree of carditis; in this case the child continues to occupy for some weeks a bed or cot much needed for fresh admissions, but when the cardiac condition seems relatively stabilised, she is necessarily discharged. It is this form of the disease which, under the name of "acute rheumatism," has fostered the erroneous idea of the arthritis being a disease in itself, whereas, indeed, it is only, like acute pleurisy in tuberculosis, an acute symptom of a grave underlying constitutional infection.

2. *Onset with chorea* is also common. These cases commonly develop endocarditis at an early stage. At any time during the course of the chorea a heart lesion may (but does not always) develop, so that a long period of uncertainty as to the future is inevitable even in the most favourable cases.

3. *Insidious onset* is too often recognised only in the past tense. The symptoms are, indeed, numerous enough—"growing pains," sore-throat, headache (too often attributed to eye-strain), pallor, wasting, and languor—but none of these may make a sufficient appeal to the hard-worked mother of a large family, and often the child is only taken to hospital for shortness of breath due to advanced cardiac disease. Into this third group of cases there is a steady drift of children from the first and second groups, who, as a result of recrudescences of infection, become the subjects of a chronic rheumatic carditis, which at the worst destroys life in a few months or weeks and at the best is likely to lead to chronic cardiac insufficiency in later life. Occupying positions intermediate between these two extremes are thousands of cases, presenting all kinds of combined symptoms and signs of cardiac infection and insufficiency, the prognostic significance of which is the only key to proper treatment.

Treatment may conveniently be considered under the same three headings as have been used above—viz., treatment directed against (*a*) acute symptoms, (*b*) chorea, (*c*) chronic carditis, it being understood, however, that the third class of treatment applies to every case of rheumatism occurring in children.

Treatment of Acute Symptoms.

The arthritis and pyrexia in an acute case rapidly yield in young subjects to treatment by salicylates. Rheumatism is rare below the age of 6 years. To a child of 8 or 10 years, 15 gr. of sod. sal. may be given with 30 gr. of sod. bicarb. every other hour for eight hours, and thereafter four-hourly until the temperature becomes normal. After this the medicine must be continued thrice daily for at least a fortnight. In the meantime the child is kept in bed between blankets, and any affected joint is supported by cotton-wool and a small many-tailed bandage. In the case of a persistently painful joint, linseed poultices applied over a single painting with tincture of iodine are useful. While any acute symptoms remain the diet should be strictly limited to milk and clear fluids, a milk diet being of great importance in the reduction and prevention of fever; meat extracts are not allowed. If tonsillitis is present the openings of the tonsillitic crypts must be repeatedly cleared by sponging with cotton-wool swabs; the mouth must be kept clean and the bowels opened daily. In the absence of all complications, rest in bed should be, if possible, continued for six weeks in all.

Chorea.—The treatment of chorea involves rest in bed and emotional restraint in all but a very few cases in which the neurotic element is so marked as to make early re-education of the first importance. The children should be encouraged to occupy themselves with sewing, knitting, or jig-saw puzzles for an hour or two every day, and a careful and discriminating nurse will know how to steer them between the varying emotions, dependent upon fatigue on the one hand and boredom on the other. Arsenic is of much use, given as Fowler's solution raised by ♏i. or ♏ii. week by week from an initial dose of ♏iv. t.d.s., until the choreic movements are in abeyance. The dose may then be continued unchanged for three weeks and then gradually lowered week by week until it is omitted altogether. Thereafter the child may start getting up, an added quarter of an hour every day being quite sufficient. During this stage, also, breathing exercises are most useful for the dissociated respiratory movements.

Prevention and Treatment of Rheumatic Carditis.

In the prophylaxis and treatment of rheumatic carditis is involved one of the chief outstanding problems of public health. Rheumatic disease stands in relation to tuberculosis of childhood, as regards frequency in about the relation of 2 to 3, but, in great contrast to tuberculosis, as yet no serious effort has been made to cope with what Dr. F. J. Poynton has rightly called a preventable disease, great destroyer of life though it is. Questions of importance in the general prevention of the disease include the improvement of housing conditions, the education of school authorities to recognise early symptoms, and the desirability of notification to enable cases to be followed up.

Management of the Individual Case.

1. *Tonsillectomy.*—Whenever it can reasonably be assumed that the tonsils may be a seat of rheumatic infection, tonsillectomy should be carried out. A fortnight's administration of salicylate of sodium thrice daily while the temperature is normal should precede operation. The evidence in favour of tonsillectomy is not yet conclusive, especially when chorea has been present, but on the whole it appears useful, especially if carried out after the first attack and before the heart is involved.

2. *Fresh Air.*—After tonsillectomy (and, in acute cases, after the completion of the treatment already described for these) a child who has had any form of rheumatic disease should be sent away from the environment in which it was contracted for from six to eight months, especially when the home is in a large town or a damp climate. This long convalescence should be insisted on whether complications in the shape of heart disease and chorea are present or not. Such a procedure often appears unreasonable to the parents, since the child seems to them and professes personally to be absolutely well. Nevertheless, it appears likely that when the allotted term of fresh air treatment is lowered beneath six to eight months, recrudescence is more than likely to occur, after the return home, in the rheumatic, just as in the tuberculous child.

3. *Rest.*—The ordinary convalescent homes, it is generally agreed, are not suited to deal with rheumatic cases. The life there is too active; rheumatic children should not be allowed to run about with those convalescent from such self-limiting diseases as pneumonia and whooping-cough. This means that accommodation should be found for them in some country home or ward where there is suitable nursing supervision. The number of available beds in this country is entirely inadequate for the thousands of children requiring them. Nevertheless, a few such places exist, of which the new heart home at Hartfield is the most recent.

As to the question of rest in bed, opinion is apparently still divided, though such authorities as Sir James Mackenzie and Dr. R. Hutchison recommend as much as six months' rest in bed while there is still evidence of infection in the heart. After observation of a number of cases during some length of time, I have come to the conclusion that the choice between rest in bed and progressive infection of the heart is in many cases unavoidable, and I have certainly never seen a child the worse for a long period of rest in bed. The children must be kept warm and should be out in the fresh air as much as possible; they should sit up in bed, since in that position the respiratory muscles act at greater advantage. Under such conditions the patients remain very contented and happy, provided that disappointment is not caused by foolish suggestions that "perhaps the doctor will let you get up this week," &c. Such suggestions, and the type of visitor who makes them, should be rigorously discouraged, since any emotional upset is very bad for rheumatic children. Treatment by rest in bed should be continued until three conditions are fulfilled: (1) The disappearance of anæmia. (2) The return of the pulse to normal, and the disappearance of the excitability characteristic of the rheumatic heart. In this connexion the return of the normal respiratory variations of the pulse is a sign of great assistance. (3) Stabilisation of the physical signs given by the heart. At this stage the borders of the heart assume fixed positions and, a sign of the greatest importance in mitral disease, the apical diastolic bruit, caused by obstruction to the smooth flow of blood over the mitral valve, ceases to vary its position in the cardiac cycle. These conditions fulfilled, the patient may be allowed gradually to get up, an added quarter of an hour being allowed daily so long as the physical signs remain constant. At the end of a month the patient will then be having an eight-hour day out of bed; but a long rest is always to be given in the middle of the day. At this stage respiratory and other physical exercises, suitably graduated, are of importance. During all this time the heart and pulse must be watched carefully. I have never seen the heart-rate do anything but rise at the commencement of getting up, though the contrary has been reported.

4. *Drugs.*—Salicylates should be given a good trial in every case where there is a recrudescence of pain or pyrexia, and will be successful in reducing these symptoms in all cases except those of advanced infective carditis. Should they fail, arsenic should be tried. The action of digitalis is uncertain, but a certain number of cases of persistent tachycardia undoubtedly respond to full doses of the tincture. In others there is no effect. Possibly the electrocardiograph may in the future differentiate more exactly the group of those cases among children who respond to digitalis from those who do not. Iron and hæmoglobin should be used during the long convalescent stage.

5. *After-care.*—The child having returned home at the end of six or eight months, regular and prolonged after-care is still necessary. When the heart has been damaged a place should be secured for the child at a school of the type that is provided by the London County Council for physically debilitated children. As a result of a long series of investigations, Dr. W. St. Lawrence, of New York, has come to the arresting conclusion that not until a given case has remained free from recrudescences for three years can its recovery be regarded as fairly safe.

MARTIN O. RAVEN, M.D. Oxf., M.R.C.P. Lond.,
Medical Officer of the Horsfall Hospital Wards,
St. Mary's Home, Broadstairs.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The following table gives some of the principal statistics for 1923 of eight urban districts :—

Name of urban district.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Willesden	169,831	18·8	9·5	0·8	1·2	1·6	20	53	3·4
Tottenham	154,300	20·0	9·1	0·9	1·1	1·8	29	58	2·3
Ilford	89,020	18·8	9·5	0·7	1·3	1·2	21	41	2·5
Edmonton ..	69,590	22·2	9·5	1·3	1·1	1·3	28	55	1·3
Heston and Isleworth .	46,505	17·4	9·8	0·9	1·0	1·6	26	55	8·3
Barry	39,710	22·9	10·7	1·1	1·1	2·0	46	78	4·6
Spenborough .	31,520	15·9	13·4	1·0	1·4	3·0	40	96	10·0
Weston-super-Mare	25,320	12·8	12·4	0·9	1·4	1·5	9	46	6·2

Willesden.

Dr. George F. Buchan gives particulars as to the effect on the attendances at the maternity and child welfare and school clinics of the system of charges imposed by the Willesden Council. At the clinics for mothers and children under 5 years the total attendances for 1923 were 23,271, showing a fall of 4234 when compared with 1922. The table given shows a sudden drop in the attendances after the imposition of a registration fee for the clinics on Oct. 1st, 1921. The withdrawal of the registration fee for the school clinic on July 10th, 1922, is followed by a gradual recovery in the attendances. The registration fee for the maternity and child welfare clinic was withdrawn on Feb. 28th, 1923. A new scheme was put into force on April 1st, 1923, with the result that the attendances at the maternity and child welfare clinic are about half, and those at the school clinic about two-thirds of the attendances recorded in 1921. The report of the school dentist shows that only 21 per cent. of the dental defects followed up were treated, and the records indicate that a very small percentage of children receive treatment through hospitals and private dental practitioners. Dr. Buchan discusses the work of the special schools at some length. One of the needs is a better ambulance service for conveying the children to these special schools. At the Leinster-road school for mentally defective children training in some simple occupation requiring manual dexterity only during the last years of school life from 14 to 16 is needed. Cobbling, chair-caning, basket-weaving, and the mechanical part of simple tailoring are given as examples. The accommodation at the Furness-road school for physically defective children is unsatisfactory and would not be considered good for normal children. To some extent this unsatisfactory accommodation is balanced by the efforts of the Invalid Children's Aid Association in sending the children to convalescent homes at the seaside and in the country. The work of the Leopold-road school for physically defective children is interfered with by the lack of ambulance accommodation. Dr. Buchan also refers to the need for a local orthopædic clinic, and his remarks are endorsed by Dr. W. J. J. Stewart, the medical superintendent of the municipal hospital, who states that since the orthopædic work at the surgical out-patient clinic was discontinued there is no place near at hand where this treatment can be carried on. When the out-patient department was closed the number of children requiring orthopædic treatment was at its highest, and the expense of transporting these crippled children to the larger London hospital clinics is quite out of the question. Dr. Buchan points out that, in addition to the physically defective children who attend the two-day special schools, there are a further two hundred or so who should be provided for in an open-air day school. It is pointed out that the present staff of sanitary inspectors is insufficient to deal with housing repairs. The Council has endeavoured to find a simple method of enforcing the adequate maintenance of property without recourse to complicated legal procedure and have interviewed the Ministry of Health on the matter.

Tottenham.

Dr. David C. Kirkhope says that the housing difficulty remains a formidable proposition. As long as there is no surplus of houses, occupied houses cannot be brought up to a satisfactory standard of repair. Dr. Kirkhope expresses his astonishment that vital statistics continue so favourable under existing housing conditions, and thinks it not surprising that there is some scepticism in the minds of those who used to regard a satisfactory environment as the essential factor in the production of low death- and sickness-rates. An exhaustive report has been made on the pollution of the river Lee with a view to getting the County Council to deal with the matter. Two main sources of pollution have been discovered. The Milk and Dairies Amendment Act, 1922, which enables the Council to refuse to register purveyors of milk unless the premises are satisfactory, has been used with advantage. In several cases registration was withheld until requirements had been complied with, and in one instance a purveyor was struck off the register. Dr. Kirkhope points out that the antenatal clinic and district maternity home are not used as much as they might be, and expresses his opinion that every primiparous woman ought to seek the advantages that a maternity hospital offers. In his school report Dr. Kirkhope refers to the considerable number of small private schools in the district. These are mostly for young children and are generally conducted in the living rooms of private dwellings. In view of overcrowding, insufficient lavatory and w.c. accommodation, he thinks all these schools should be brought under the supervision of the local education authority. Arrangements have been made for the treatment of discharging ears by ionisation, and Dr. Kirkhope is in the happy position of being able to report that the clinics provided by the committee and the arrangements made with other authorities appear practically to cover every phase of medicine and surgery such as is necessary for the treatment of diseases of childhood.

Ilford.

Dr. A. H. G. Burton says the maternity home has proved its usefulness in spite of its not being entirely suitable for the purpose. He is, therefore, glad to report that the provision of a modern maternity home will be accomplished in the course of a few months. Dr. Burton states that an investigation into the "Milne" treatment of scarlet fever has shown that the method is an unsound one, and that the treatment (*a*) does not prevent "return" cases, (*b*) does not prevent the spread of infection to susceptible persons, and (*c*) does not prevent secondary complications. Dr. Burton states that the new milk orders have not met with any marked success, and thinks there will not be much improvement in the bacterial cleanliness of milk until a standard is fixed below which no milk must be retailed at all. As the result of a newspaper scare with regard to the retailing of tinned meats from army dumps, an inspection was made of grocers' stocks, but no justification was found for the scare in Ilford. Dr. Burton refers with satisfaction to the fact that 93 per cent. of the defects of vision detected among the school-children were remedied by the work of the ophthalmic surgeon, Mr. R. S. Charsley. The provision of an open-air school for Ilford is now under the consideration of the education committee. There is still no adequate provision for mentally defective children.

Edmonton.

Dr. H. W. Harding gives as the outstanding needs of his district: (1) more housing accommodation; (2) more travelling facilities; (3) a more hygienic method of disposing of house refuse than the present one of dumping; (4) a satisfactory method of treating the sewage. Dr. Harding states that there has been a set back in cleanliness in the schools, and associates this with the housing conditions. It is hoped to deal with the sewage problem during the present year. The recent circular from the Ministry with regard to cancer was discussed by the Edmonton Medical Society, which came to the conclusion that the local facilities for consultations, pathological examinations, treatment, and the transport of patients were satisfactory, that the public were being sufficiently educated in the matter by the press, &c., and that there was a feeling of nervous apprehension among the population that rendered special propaganda work undesirable. A mothercraft class has been started at the day nursery. Senior girls in groups of six attend one day per week for instruction from 9 to 10.45 A.M. for a period of six weeks. Sixty girls will pass through the class every term. The experiment has been a success and the girls are keenly interested in the work.

Heston and Isleworth.

Dr. Elwin H. T. Nash mentions an unusual incident in connexion with a well used by a dairyman for cooling purposes. The drawpipe of the well was eaten away and the water was acid. The cause of the trouble was found to be the effluent from some neighbouring works, which could not be discharged into the sewers on account of its acidity and colour, and was in consequence discharged into a deep soak-away in the gravel. The proprietors of the works provided the dairyman with a refrigerating plant and ultimately found a method for removing the colour and neutralising the acidity of their effluent. Under the heading of water-supply the health department have done useful work by securing the substitution of 108 taps direct from the main in lieu of water-supplies drawn from inaccessible and uncovered cisterns. Dr. Nash, in common with other medical officers of health of large urban districts, thinks the control of the midwives should be in the hands of the district council. Antenatal work has been hitherto negligible in amount owing to the lack of suitable premises. Negotiations for the latter are in progress. In the school report Dr. Nash gives some examples of satisfactory results obtained by persistent and persevering following-up. He refers to the unsatisfactory treatment of discharging ears and would like to see ionisation established. Dr. Nash points out that a large proportion of enlarged tonsils disappear after a septic mouth has been cleaned up, but, if operation is necessary, he is entirely opposed to slicing and favours complete enucleation. Only a small proportion of the children requiring dental treatment receive it. Dr. Nash would like to see orthodontic work established in the schools by coöperation between the school dentists and the consulting orthodontist at the hospital.

Barry.

Dr. Percy W. Kent says the present distressing housing conditions will exist until private enterprise is again available, although the council are doing their best to meet the demand for houses. Dr. Kent regards the maternity and child welfare work as the most important branch of the council's public health activities—even more important than remedying defects in school life. Dr. G. H. Winch, medical officer of the Glamorgan County V.D. Clinic at Barry, draws special attention to the regular attendance of patients, both male and female, in their evident keenness to be thoroughly treated and cured. Old-standing cases of syphilis and gonorrhœa still drop in for treatment and state that they have only just heard of the clinics. Dr. Winch concludes that there is even yet insufficient propaganda work. He further mentions the inadequate provision made for the treatment of seamen, especially in foreign ports. In the school report Dr. Kent mentions a new departure—namely, an Education Week, held in June. The programme included special excursions. The schools and school clinics were open for parents to see the work in progress. An illustrated guide was issued which included a brief history of the school service of Barry. The "week" proved a great success. Large numbers of persons attended and displayed a keen interest in the work of schools and clinics.

Spenborough.

Dr. Lawrence Pick shows that Spenborough, Halifax, and Keighley are the only districts in the West Riding where there are more males engaged in metal than in textile work. The census showed there were 2994 female and 1855 male textile workers, whilst there were 3145 male metal workers. In dealing with the work of the child welfare centres, Dr. Pick says there is a tendency for parents to regard them as hospital out-patient departments. Rather more dried milk was sold than in the previous year, but over 500 lb. less was supplied free. The council are negotiating for a site for a public abattoir. An inspection of the cowsheds shows that a considerable number have an air space of under 400 cubic feet per cow. Some of them are said to be in total darkness when the door is shut. During the year the Education Committee made satisfactory arrangements with neighbouring authorities for a dental service for the school-children and for the X ray treatment of ringworm. Cleanliness inspection among the school-children shows that about 4 per cent. of the parents are quite indifferent to verminous conditions in their children. The time is come, says Dr. Pick, when more vigorous action will have to be taken.

Weston-super-Mare.

Dr. John Wallace reports the satisfactory completion of the Banwell water scheme since the close of the year. The old water-supply was becoming increasingly hard and brackish. The provision of a pulverising plant has, it is hoped, satisfactorily provided for the disposal of refuse and done away with the need for tips. Suitable accommodation for the health department and a new infectious diseases hospital are among the outstanding needs. All the slaughtering is done at the public abattoir, and humane killers are used for cattle and pigs. The sanitary inspector points out, however, that a considerable amount of meat killed outside the town is brought into it.

SCHOOL MEDICAL WORK IN LONDON.

Sir William Hamer's report on school medical [illegible] in London during 1923 is good reading. Two hu[illegible] and eighteen thousand children obtained treat[illegible] This figure has kept on growing in response to [illegible] demand, and will probably continue to grow [illegible] high-water mark is reached, when preventive [illegible] ought to make themselves felt and the [illegible] will subside. Dr. C. J. Thomas, who is resp[illegible] this department, has good c[illegible] to [illegible] himself on the efficiency of an [illegible] with the medical inspection o[illegible] over [illegible] children, and the medical t[illegible]ent [illegible] of those requiring it. E[illegible] children in need of spectac[illegible] [illegible] figure has never been to[illegible] and surely indicates a high [illegible] of [illegible]

The work in London [illegible] The greatest improvement [illegible] direction of personal cleanli[illegible] The percentage of elder [illegible] heads now stands at over [illegible] of the school nurses is ed[illegible] steady improvement which [illegible] in character is to be pr[illegible] improvement due to comp[illegible] evanescent when the comp[illegible] The good work of the Council's [illegible]

in the progressive improvement in the dental condition of the 12-year old group. The number of children with four or more decayed teeth in this group has dwindled from 10 to less than 3 per cent., while of the junior scholarship candidates the number requiring dental treatment has fallen from 39 per cent. in 1913 to 7 per cent. to-day. Dr. E. O. Lewis's important investigation into the question of whether enlarged tonsils in children increase susceptibility to infectious disease, and whether susceptibility is decreased by removal of enlarged tonsils, showed the incidence of infectious disease amongst the school population generally to be 28 per cent., while upon those who had had enlarged tonsils removed it was only 4·8 per cent. On the other hand, Kaiser's[1] investigation into the effect of tonsillectomy on the general health of 1200 children in New York, as compared with an equal number of controls during the same period who were not operated on but in whom the indications for operation were the same, showed that the incidence of scarlet fever was not affected, though the severity of the attack may have been reduced.

The charts published appear to dispose effectively of a most interesting hypothetical connexion between the flea and scarlet fever; indeed, on the chart scarlet fever appears to increase as the activity of the Council's cleansing scheme disperses the flea.

That scarlet fever is a throat infection appears to be probable from the results of the Dick experiments and investigations in America, which are disclosing the possibility that an active immunisation of some sort will shortly be available. In this connexion it is interesting to note that not in one of the 230 cases in London certified as suffering from chorea was the disease a sequel of scarlet fever; indeed, Sir William Hamer considers that the relationship between chorea and rheumatism has been somewhat exaggerated in the past judging by the age distribution and the low incidence of cardiac disease among the so-called choreic cases. "The general features of the statistics support the conclusion suggested by the clinical examination of several cases, that there is an increasing tendency to certify as chorea conditions of purely neurogenic character. The substantial increase in the number of girls suffering from chorea is another proof that what hitherto was regarded as simply adolescent instability is now called chorea . . . that there is of late an increase of nervous trouble among children is shown by further analysis of the figures." From 1920 to 1923, 8·21, 7·8, 8·44, and 10·05 per cent. respectively of the out-of-school cases were absent owing to nervous trouble. In 1920 the proportion of out-of-school cases suffering from chorea was only 7·4 per cent., in 1921 it was 8·19 per cent., 9·2 per cent. in 1922, and in 1923 it was 9 per cent. Sir William Hamer considers that many of the cases of chorea would be more appropriately classified under nervous disorders, and puts forward a suggestion that the effect of air-raids on a child of 8 or younger might be the cause of the increase of nervous instability among the adolescent; it is quite possible that the nervous apprehension obtaining in most homes during the war is responsible for such a marked increase in those two sets of figures.

While the number of children from 3 to 5 years of age in the infants' departments of the elementary schools has increased to over 50,000, it is unfortunate that the number of nursery schools in London has remained the same. The Geddes report showed how inadequate was the provision for these children in the elementary schools. Dr. Margaret Hogarth, outlining the differences between the provision made for this group in the two types of school, sums up the fundamental difference in the fact that the amenities of the nursery school approach more nearly that of a middle-class home, but as far as main buildings are concerned, for summer and winter use, "few can be compared with the newer type of elementary school with French windows opening into a sunny playground, a large airy hall, and well warmed cloakroom where wet clothes and boots can be dried. . . The nursery school recognises that personal attention to the requirements of the child is just as important as attention to his mental requirements." There is no doubt that the inadequate provision for the physical and mental requirements of this age group is due to the fact that the teachers employed have had no special training to meet the case. The requirements of children from 2 to 5 years of age differ materially from those of older children, and the question of a proper training for their supervision is equally one for medical and educational consideration. A scheme for the special training of London County Council teachers in this work is needed and would not be difficult to formulate. It is to be hoped that London will see its way to tackle this really urgent question and to remove the unsightly gap which the absence of suitable medical and educational provision for children of 2 to 5 years of age undoubtedly leaves in the County Council's excellent scheme for child welfare and social progress.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 30TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 51: scarlet fever, 1384; diphtheria, 595; enteric fever, 96; pneumonia, 383; puerperal fever, 37, cerebro-spinal fever, 10; acute poliomyelitis, 37: acute polio-encephalitis, 5: encephalitis lethargica, 55; continued fever, 1; dysentery, 9; ophthalmia neonatorum, 107. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 6 deaths from enteric fever, none from small-pox, 9 from scarlet fever, 22 from diphtheria, 12 from measles, 20 from influenza. In London itself the diphtheria deaths numbered 8.

NOTE ON THE DESTRUCTION OF RATS BY EXHAUST GAS.

By D. B. Blacklock, M.D. Edin.,
DIRECTOR, SIR ALFRED LEWIS JONES RESEARCH LABORATORY, FREETOWN;
AND
W. H. Peacock, M.B., B.S. Durh., D.P.H.,
SENIOR SANITARY OFFICER, SIERRA LEONE.

The essentials of a satisfactory agent for the destruction of wild rats are that it should be highly lethal to rats, relatively innocuous to man, devoid of deleterious effects on cargo, furnishings, and fittings, and that it should be cheap and simple in application. The agents at present in use for this purpose—namely, sulphur dioxide, hydrogen cyanide[1] and carbon monoxide as generated by the Giemsa-Nocht apparatus—all fail in one or other of these essentials. We believe that the following experiments demonstrate that in the exhaust gases of the petrol engine we possess ready to our hand an agent which for the destruction of the wild rats comes nearer to the fulfilment of these requirements than any hitherto employed. The petrol used by us was either "Sphinx" or "Tydol," but other brands may doubtless give similar results.

Experiments with Motor-car Exhaust on Rats.

In a Box.—The gas was led from the exhaust pipe of an Overland car of 16–18 h.p., by a length of rubber tubing, through the lid of a box which measured 18 × 12 × 12 inches. Each rat used for experiment was introduced in a small cage into the end of the box remote from the inlet tube. The results are shown in Table I.

1 ,, ...	3	,,	2	,,
45 seconds	—	—	1	Collapsed.
30 ,, ...	2	1 dead 1 collapsed	—	—

In these experiments all rats, brown or black, were killed by one minute's exposure to the gas.

For comparison the effects of sulphur dioxide from a hand-driven Clayton apparatus were tested. The optimum number of revolutions of the fan for this machine was ascertained to be about 50 per minute. Below and above this rate the lethal effect on wild rats fell away. In Table II. are given the results of using sulphur dioxide from the machine.

TABLE II.—*Showing the Effects of Sulphur Dioxide on Wild Rats in Box Experiments.*

	Number used.	Result.	Number used.	Result.
5 minutes	1	Dead.	—	—
3 ,, ...	1	,,	—	—
2 ,, ...	1	Alive.	2	Alive.
1 ,, ...	2	,,	3	,,

In these experiments no rat, brown or black, was killed by one minute's exposure to the sulphur dioxide gas.

In Drains.—A concrete drain was roofed in with planks and covered with earth. It was tested in lengths varying from 4 ft. to 81 ft. Rats were liberated into the drain at various points and the gas turned on; or, again, they were confined at each end of the drain or at chosen distance from the inlet end. The gases were tested both up hill and down hill. Contrary to expectation, the exhaust gas proved superior to Clayton gas even down hill in a steep drain 81 ft. long. Two black rats at the lower end of the drain were quite unaffected by 30 minutes' application of the Clayton machine to the upper end of the drain, whereas this exposure to exhaust gas killed such rats outright, and even 18 minutes' exposure caused collapse. *Mus norvegicus* was unaffected by 30 minutes' exposure to the Clayton, while the same period of the exhaust either killed or caused collapse. The introduction of exhaust gas into a drain did not drive the rats out, whereas the Clayton gas did so. Again, rats showed no reluctance to enter the drain when full of exhaust gas; they declined to enter when it was full of sulphur dioxide.

The fact that rats tend to try to escape from the sulphur dioxide fumes indicates that in warehouses and ships undergoing fumigation they would make for a more respirable atmosphere. As sulphur dioxide is very slow in its effects they have ample time to seek out the least poisonous areas. This, taken in conjunction with the difficulty of applying sulphur dioxide equally to all parts of a ship, helps to explain the frequency with which wild rats survive such fumigation.

In a Sealed Chamber.—A room constructed of concrete was used, the windows being sealed with brown paper having inspection windows inset. The rats were distributed in cages on the floor, near the ceiling, and at the inspection windows. The door was sealed and the gas introduced through a circular aperture cut to fit the delivery tube. The capacity of the chamber was 2160 cubic feet. Several experiments were carried out with each gas.

Exhaust gas was applied to the chamber for half an hour: at the end of that time, on opening up, of eight rats used five were dead and three collapsed. The gas was next applied for one hour; at the end of this experiment all the rats used, five in number, were dead.

Sulphur dioxide was applied to the chamber for half an hour with the fan rotating at 50 revs. p.m.; at the end of that time, on opening up, of eight rats used, four black and four brown, none were dead. Applied for half an hour at 50 revs. p.m., followed by six hours under seal, the gas killed only two out of eight rats. Applied for half an hour at 100 revs. p.m., followed by six hours under seal, the gas killed none of eight rats exposed, four black and four brown. The unsatisfactory results obtained from the Clayton apparatus led us to discard it and use sulphur candles for future comparisons.

By making use of the inspection windows the different effects of the two gases on the rats could be studied and timed. It was seen that rats exposed to the exhaust gas showed no sign of any disturbance up to a period of 15 minutes: this was the earliest time at which the effects began, the latest being 25 minutes. The first effect noted was restlessness; the rat suddenly began to run about anxiously; in a minute or so it collapsed, took a few deep gasps, and died. Rats removed from the gas atmosphere immediately after collapsing on the bottom of the cage recovered with great regularity, but if not immediately removed they invariably died without further struggle. With sulphur dioxide as administered by the Clayton hand machine the rats showed slight lacrymation and respiratory effects; with the candles burning they began after half an hour to lacrymate and cough. They moved about anxiously, then huddled themselves up in a corner; soon they moved about again, becoming more and more disturbed in their respiration. The action of the gas was productive of great distress, and yet was very slow in its ultimate effect. Even with six candles burning, which is much in excess of the number stated to be requisite, it required three hours to produce the death of wild rats. The animals' eyes were then covered by an opaque film, and the animals were much contorted. All the evidence from these experiments shows that in exhaust gas from a petrol engine we have an agent which is extremely lethal to rats, which is rapid in its action, and which kills with the minimum of suffering.

Experiments with Motor Launch Exhaust on Rats.

In Box.—The exhaust here was only obtainable mixed with the cooling water of a 10 h.p. engine; the gas and water were discharged through the same pipe. Preliminary experiments proved that with the water turned off the exhaust gas was fatal in one minute. There was some blackening from the carbon when so used. It was found that by allowing the water to issue with the exhaust gas the lethal effect of the gas was not impaired, and the gas was clean and produced no blackening effect.

In Ship's Lighters.—An empty lighter was used for the next experiment. This had a watertight hold of 2304 cubic feet capacity. It was the usual type of lighter used for loading at Freetown, with tightly fitting hatches and tarpaulins battened down. The experimental cages were distributed high and low in it, and the exhaust gas with water passed in a tube under one of the hatches supported on a wedge, the tarpaulin being drawn tightly round it; the gas entered the hold at three-quarters of its depth. Six rats, three black and three brown, each in a separate cage were used. The engine of the launch was run for an hour and the hatches opened. The gas rapidly escaped in an easily visible cloud, and all the rats were found to be dead. After the experiment had been going on for 35 minutes a rat was lowered into the hold for five minutes; when removed it was collapsed on the bottom of the cage but still breathing slowly, and it recovered. It is clear that even so early as this the concentration of the gas in the empty lighter was almost sufficiently high to have a lethal effect.

The lighter was then loaded up with palm kernels in hessian bags and the hatches put in position; one hatch at each end was then lifted and 12 rats were admitted free to the hold, eight in the far end and four in the near end. The hatches were replaced, covered with the tarpaulins, and battened down. Exhaust gas was run in under one hatch for an hour. The hatches were raised, and after the lapse of less than ten minutes the cargo was removed. Of the 12 rats liberated all were found: ten were dead and two collapsed; these recovered later.

These experiments show that rats free even in a loaded lighter are rarely capable of escaping from the lethal action of the gas by sheltering in crevices between the cargo. It appears probable that a slightly longer exposure would have killed 100 per cent. of the rats. Considering that the whole operation in this experiment from the time of commencing fumigation to the time when the labourers started

in the progressive improvement in the dental condition of the 12-year old group. The number of children with four or more decayed teeth in this group has dwindled from 10 to less than 3 per cent., while of the junior scholarship candidates the number requiring dental treatment has fallen from 39 per cent. in 1913 to 7 per cent. to-day. Dr. E. O. Lewis's important investigation into the question of whether enlarged tonsils in children increase susceptibility to infectious disease, and whether susceptibility is decreased by removal of enlarged tonsils, showed the incidence of infectious disease amongst the school population generally to be 28 per cent., while upon those who had had enlarged tonsils removed it was only 4·8 per cent. On the other hand, Kaiser's[1] investigation into the effect of tonsillectomy on the general health of 1200 children in New York, as compared with an equal number of controls during the same period who were not operated on but in whom the indications for operation were the same, showed that the incidence of scarlet fever was not affected, though the severity of the attack may have been reduced.

The charts published appear to dispose effectively of a most interesting hypothetical connexion between the flea and scarlet fever; indeed, on the chart scarlet fever appears to increase as the activity of the Council's cleansing scheme disperses the flea.

That scarlet fever is a throat infection appears to be probable from the results of the Dick experiments and investigations in America, which are disclosing the possibility that an active immunisation of some sort will shortly be available. In this connexion it is interesting to note that not in one of the 230 cases in London certified as suffering from chorea was the disease a sequel of scarlet fever; indeed, Sir William Hamer considers that the relationship between chorea and rheumatism has been somewhat exaggerated in the past judging by the age distribution and the low incidence of cardiac disease among the so-called choreic cases. "The general features of the statistics support the conclusion suggested by the clinical examination of several cases, that there is an increasing tendency to certify as chorea conditions of purely neurogenic character. The substantial increase in the number of girls suffering from chorea is another proof that what hitherto was regarded as simply adolescent instability is now called chorea . . . that there is of late an increase of nervous trouble among children is shown by further analysis of the figures." From 1920 to 1923, 8·21, 7·8, 8·44, and 10·05 per cent. respectively of the out-of-school cases were absent owing to nervous trouble. In 1920 the proportion of out-of-school cases suffering from chorea was only 7·4 per cent., in 1921 it was 8·19 per cent., 9·2 per cent. in 1922, and in 1923 it was 9 per cent. Sir William Hamer considers that many of the cases of chorea would be more appropriately classified under nervous disorders, and puts forward a suggestion that the effect of air-raids on a child of 8 or younger might be the cause of the increase of nervous instability among the adolescent; it is quite possible that the nervous apprehension obtaining in most homes during the war is responsible for such a marked increase in those two sets of figures.

While the number of children from 3 to 5 years of age in the infants' departments of the elementary schools has increased to over 50,000, it is unfortunate that the number of nursery schools in London has remained the same. The Geddes report showed how inadequate was the provision for these children in the elementary schools. Dr. Margaret Hogarth, outlining the differences between the provision made for this group in the two types of school, sums up the fundamental difference in the fact that the amenities of the nursery school approach more nearly that of a middle-class home, but as far as main buildings are concerned, for summer and winter use, "few can be compared with the newer type of elementary school with French windows opening into a sunny playground, a large airy hall, and well warmed cloakroom where wet clothes and boots can be dried. . . The nursery school recognises that personal attention to the requirements of the child is just as important as attention to his mental requirements." There is no doubt that the inadequate provision for the physical and mental requirements of this age group is due to the fact that the teachers employed have had no special training to meet the case. In these experiments no rat, brown or black, was killed by one minute's exposure to the sulphur dioxide gas.

In Drains.—A concrete drain was roofed in with planks and covered with earth. It was tested in lengths varying from 4 ft. to 81 ft. Rats were liberated into the drain at various points and the gas turned on; or, again, they were confined at each end of the drain or at chosen distance from the inlet end. The gases were tested both up hill and down hill. Contrary to expectation, the exhaust gas proved superior to Clayton gas even down hill in a steep drain 81 ft. long. Two black rats at the lower end of the drain were quite unaffected by 30 minutes' application of the Clayton machine to the upper end of the drain, whereas this exposure to exhaust gas killed such rats outright, and even 18 minutes' exposure caused collapse. *Mus norvegicus* was unaffected by 30 minutes' exposure to the Clayton, while the same period of the exhaust either killed or caused collapse. The introduction of exhaust gas into a drain did not drive the rats out, whereas the Clayton gas did so. Again, rats showed no reluctance to enter the drain when full of exhaust gas; they declined to enter when it was full of sulphur dioxide.

The fact that rats tend to try to escape from the sulphur dioxide fumes indicates that in warehouses and ships undergoing fumigation they would make for a more respirable atmosphere. As sulphur dioxide is very slow in its effects they have ample time to seek out the least poisonous areas. This, taken in conjunction with the difficulty of applying sulphur dioxide equally to all parts of a ship, helps to explain the frequency with which wild rats survive such fumigation.

In a Sealed Chamber.—A room constructed of concrete was used, the windows being sealed with brown paper having inspection windows inset. The rats were distributed in cages on the floor, near the ceiling, and at the inspection windows. The door was sealed and the gas introduced through a circular aperture cut to fit the delivery tube. The capacity of the chamber was 2160 cubic feet. Several experiments were carried out with each gas.

Exhaust gas was applied to the chamber for half an hour; at the end of that time, on opening up, of eight rats used five were dead and three collapsed. The gas was next applied for one hour; at the end of this experiment all the rats used, five in number, were dead.

Sulphur dioxide was applied to the chamber for half an hour with the fan rotating at 50 revs. p.m.; at the end of that time, on opening up, of eight rats used, four black and four brown, none were dead. Applied for half an hour at 50 revs. p.m., followed by six hours under seal, the gas killed only two out of eight rats. Applied for half an hour at 100 revs. p.m., followed by six hours under seal, the gas killed none of eight rats exposed, four black and four brown. The unsatisfactory results obtained from the Clayton apparatus led us to discard it and use sulphur candles for future comparisons.

By making use of the inspection windows the different effects of the two gases on the rats could be studied and timed. It was seen that rats exposed to the exhaust gas showed no sign of any disturbance up to a period of 15 minutes; this was the earliest time at which the effects began, the latest being 25 minutes. The first effect noted was restlessness; the rat suddenly began to run about anxiously; in a minute or so it collapsed, took a few deep gasps, and died. Rats removed from the gas atmosphere immediately after collapsing on the bottom of the cage recovered with great regularity, but if not immediately removed they invariably died without further struggle. With sulphur dioxide as administered by the Clayton hand machine the rats showed slight lacrymation and respiratory effects; with the candles burning they began after half an hour to lacrymate and cough. They moved about anxiously, then huddled themselves up in a corner; soon they moved about again, becoming more and more disturbed in their respiration. The action of the gas was productive of great distress, and yet was very slow in its ultimate effect. Even with six candles burning, which is much in excess of the number stated to be requisite, it required three hours to produce the death of wild rats. The animals' eyes were then covered by an opaque film, and the animals were much contorted. All the evidence from these experiments shows that in exhaust gas from a petrol engine we have an agent which is extremely lethal to rats, which is rapid in its action, and which kills with the minimum of suffering.

Experiments with Motor Launch Exhaust on Rats.

In Box.—The exhaust here was only obtainable mixed with the cooling water of a 10 h.p. engine; the gas and water were discharged through the same pipe. Preliminary experiments proved that with the water turned off the exhaust gas was fatal in one minute. There was some blackening from the carbon when so used. It was found that by allowing the water to issue with the exhaust gas the lethal effect of the gas was not impaired, and the gas was clean and produced no blackening effect.

In Ship's Lighters.—An empty lighter was used for the next experiment. This had a watertight hold of 2304 cubic feet capacity. It was the usual type of lighter used for loading at Freetown, with tightly fitting hatches and tarpaulins battened down. The experimental cages were distributed high and low in it, and the exhaust gas with water passed in a tube under one of the hatches supported on a wedge, the tarpaulin being drawn tightly round it; the gas entered the hold at three-quarters of its depth. Six rats, three black and three brown, each in a separate cage were used. The engine of the launch was run for an hour and the hatches opened. The gas rapidly escaped in an easily visible cloud, and all the rats were found to be dead. After the experiment had been going on for 35 minutes a rat was lowered into the hold for five minutes; when removed it was collapsed on the bottom of the cage but still breathing slowly, and it recovered. It is clear that even so early as this the concentration of the gas in the empty lighter was almost sufficiently high to have a lethal effect.

The lighter was then loaded up with palm kernels in hessian bags and the hatches put in position; one hatch at each end was then lifted and 12 rats were admitted free to the hold, eight in the far end and four in the near end. The hatches were replaced, covered with the tarpaulins, and battened down. Exhaust gas was run in under one hatch for an hour. The hatches were raised, and after the lapse of less than ten minutes the cargo was removed. Of the 12 rats liberated all were found: ten were dead and two collapsed; these recovered later.

These experiments show that rats free even in a loaded lighter are rarely capable of escaping from the lethal action of the gas by sheltering in crevices between the cargo. It appears probable that a slightly longer exposure would have killed 100 per cent. of the rats. Considering that the whole operation in this experiment from the time of commencing fumigation to the time when the labourers started

in the progressive improvement in the dental condition of the 12-year old group. The number of children with four or more decayed teeth in this group has dwindled from 10 to less than 3 per cent., while of the junior scholarship candidates the number requiring dental treatment has fallen from 39 per cent. in 1913 to 7 per cent. to-day. Dr. E. O. Lewis's important investigation into the question of whether enlarged tonsils in children increase susceptibility to infectious disease, and whether susceptibility is decreased by removal of enlarged tonsils, showed the incidence of infectious disease amongst the school population generally to be 28 per cent., while upon those who had had enlarged tonsils removed it was only 4·8 per cent. On the other hand, Kaiser's[1] investigation into the effect of tonsillectomy on the general health of 1200 children in New York, as compared with an equal number of controls during the same period who were not operated on but in whom the indications for operation were the same, showed that the incidence of scarlet fever was not affected, though the severity of the attack may have been reduced.

The charts published appear to dispose effectively of a most interesting hypothetical connexion between the flea and scarlet fever; indeed, on the chart scarlet fever appears to increase as the activity of the Council's cleansing scheme disperses the flea.

That scarlet fever is a throat infection appears to be probable from the results of the Dick experiments and investigations in America, which are disclosing the possibility that an active immunisation of some sort will shortly be available. In this connexion it is interesting to note that not in one of the 230 cases in London certified as suffering from chorea was the disease a sequel of scarlet fever; indeed, Sir William Hamer considers that the relationship between chorea and rheumatism has been somewhat exaggerated in the past judging by the age distribution and the low incidence of cardiac disease among the so-called choreic cases. "The general features of the statistics support the conclusion suggested by the clinical examination of several cases, that there is an increasing tendency to certify as chorea conditions of purely neurogenic character. The substantial increase in the number of girls suffering from chorea is another proof that what hitherto was regarded as simply adolescent instability is now called chorea . . . that there is of late an increase of nervous trouble among children is shown by further analysis of the figures." From 1920 to 1923, 8·21, 7·8, 8·44, and 10·05 per cent. respectively of the out-of-school cases were absent owing to nervous trouble. In 1920 the proportion of out-of-school cases suffering from chorea was only 7·4 per cent., in 1921 it was 8·19 per cent., 9·2 per cent. in 1922, and in 1923 it was 9 per cent. Sir William Hamer considers that many of the cases of chorea would be more appropriately classified under nervous disorders, and puts forward a suggestion that the effect of air-raids on a child of 8 or younger might be the cause of the increase of nervous instability among the adolescent; it is quite possible that the nervous apprehension obtaining in most homes during the war is responsible for such a marked increase in those two sets of figures.

While the number of children from 3 to 5 years of age in the infants' departments of the elementary schools has increased to over 50,000, it is unfortunate that the number of nursery schools in London has remained the same. The Geddes report showed how inadequate was the provision for these children in the elementary schools. Dr. Margaret Hogarth, outlining the differences between the provision made for this group in the two types of school, sums up the fundamental difference in the fact that the amenities of the nursery school approach more nearly that of a middle-class home, but as far as main buildings are concerned, for summer and winter use, "few can be compared with the newer type of elementary school with French windows opening into a sunny playground, a large airy hall, and well warmed cloakroom where wet clothes and boots can be dried. . . The nursery school recognises that personal attention to the requirements of the child is just as important as attention to his mental requirements." There is no doubt that the inadequate provision for the physical and mental requirements of this age group is due to the fact that the teachers employed have had no special training to meet the case. The requirements of children from 2 to 5 years of age differ materially from those of older children, and the question of a proper training for their supervision is equally one for medical and educational consideration. A scheme for the special training of London County Council teachers in this work is needed and would not be difficult to formulate. It is to be hoped that London will see its way to tackle this really urgent question and to remove the unsightly gap which the absence of suitable medical and educational provision for children of 2 to 5 years of age undoubtedly leaves in the County Council's excellent scheme for child welfare and social progress.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 30TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 51: scarlet fever, 1384; diphtheria, 595; enteric fever, 96; pneumonia, 383; puerperal fever, 37, cerebro-spinal fever, 10; acute poliomyelitis, 37: acute polio-encephalitis, 5: encephalitis lethargica, 55; continued fever, 1; dysentery, 9; ophthalmia neonatorum, 107. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 6 deaths from enteric fever, none from small-pox, 9 from scarlet fever, 22 from diphtheria, 12 from measles, 20 from influenza. In London itself the diphtheria deaths numbered 8.

NOTE ON THE DESTRUCTION OF RATS BY EXHAUST GAS.

By D. B. Blacklock, M.D. Edin.,
DIRECTOR, SIR ALFRED LEWIS JONES RESEARCH LABORATORY, FREETOWN;
AND
W. H. Peacock, M.B., B.S. Durh., D.P.H.,
SENIOR SANITARY OFFICER, SIERRA LEONE.

The essentials of a satisfactory agent for the destruction of wild rats are that it should be highly lethal to rats, relatively innocuous to man, devoid of deleterious effects on cargo, furnishings, and fittings, and that it should be cheap and simple in application. The agents at present in use for this purpose—namely, sulphur dioxide, hydrogen cyanide[1] and carbon monoxide as generated by the Giemsa-Nocht apparatus—all fail in one or other of these essentials. We believe that the following experiments demonstrate that in the exhaust gases of the petrol engine we possess ready to our hand an agent which for the destruction of the wild rats comes nearer to the fulfilment of these requirements than any hitherto employed. The petrol used by us was either "Sphinx" or "Tydol," but other brands may doubtless give similar results.

Experiments with Motor-car Exhaust on Rats.

In a Box.—The gas was led from the exhaust pipe of an Overland car of 16–18 h.p., by a length of rubber tubing, through the lid of a box which measured 18 × 12 × 12 inches. Each rat used for experiment was introduced in a small cage into the end of the box remote from the inlet tube. The results are shown in Table I.

handling the cargo after opening up only occupied an hour and ten minutes, it appears a very promising method.

A local firm supplied us with a representative series of articles of export and import; these were exposed to the exhaust gases for six and a half hours. The results showed that the gases had no ill-effect on such articles of food as lard, butter, sugar, cocoa-beans, potatoes, flour, bacon, salt, ground nuts, palm kernels, palm oil, onions, and other commodities. No deleterious effect was observed, in texture or in colour, on a large range of cotton, silk, and woollen articles also exposed for six and a half hours to the gas.

Experiments to Test the Penetrating Power of the Exhaust Gas.

These experiments were designed to show whether the gas could gain access to rats concealed in bales and in packing cases and cupboards on board ship or in store sheds.

Rats enclosed in one or in many folds of hessian bags were invariably found dead after one minute's treatment in the experimental box. Similarly rats enclosed in a cardboard box provided only with a slit-like aperture too small for the rats to escape from were killed in one minute. Sugar, flour, ground nuts, salt, rice, bacon, and many other articles are packed in hessian bags. It is clear, then, that this gas possesses great power of penetration, and that rats are not protected from it by any of the ordinary packing methods used.

Effects on Human Beings.

During the whole of the experiments no ill-effect on man was ever observed, although many uneducated natives were employed, and of necessity were somewhat exposed to the gas. The gas which had diffused so thoroughly in one hour as to kill all the rats in the empty lighter and 10 out of 12 in the loaded lighter cleared rapidly when the hatches were removed. When the visible cloud had disappeared from the hold men were able to enter it with safety.

We have unfortunately not had an opportunity of testing the method in large ships, but there seems no reason to suppose that it is not applicable to them. It could be applied by dividing the ship into sections and using several motor launches simultaneously. Indicator rats should in all fumigation work be laid down in remote parts of the place to be treated, and used as tests at opening up before entry.

Summary and Conclusions.

1. The exhaust gas of the petrol engine of a motor-car or launch is very fatal to wild rats, black or brown.

2. It is relatively safe for human beings to work with.

3. It does not damage cargo, fittings, or furnishings.

4. Its use involves no apparatus which is not universally obtainable in any port; it is cheap, easy of application, and rapid in its action.

5. It clears quickly on opening up after application and leaves no unpleasant odour behind.

Acknowledgments are due to Mr. L. White, Messrs. Elder Dempster and Co., Ltd., for placing a launch and lighter at our disposal, and to Captain Pirie and Mr. Henning for much assistance in arranging the details of the experiments. We are also indebted to Messrs. Forbes-Gatherum and McAlister, of the African and Eastern Trade Corporation, Ltd., who kindly undertook to furnish us with samples of produce and goods for testing, and who reported on the effects of the gas on the articles after the tests.

MEDICAL CERTIFICATION OF CAUSE OF DEATH.

ISSUE OF A NEW FORM.

It is exactly 50 years since the Births and Deaths Registration Act of 1874 came into force, and with it the present form of Medical Certificate of the Cause of Death. This form relieved the practitioner from the obligation to certify, as of his own knowledge, the age of the deceased, and no longer required the practitioner to certify the fact of death. The revision of the form of medical certificate has now been taken a little further, chiefly for the purpose of removing certain ambiguities which in practice were found to attach to the old form. A new form has been drafted and will shortly be issued which, while requiring no more information than the old, provides for that information being stated in a more direct and unambiguous manner.

In reference to the form of the statement indicating whether the fact of death is certified by the medical practitioner on his own knowledge or merely reported on the information of the relatives, in the old form this statement and the statement as to the date of death are combined in words running as follows:—

"(I hereby Certify) . . . .; that he died .... on the .... day of .... 19.... ";

while a note to the asterisk states: "Should the Medical Attendant not feel justified in taking upon himself the responsibility of certifying the *fact* of Death, he may here insert the words '*as I am informed*.'"

In the first place, this arrangement places upon the certifying practitioner the duty of writing in the words "as I am informed" in what must be the great majority of certificates given; and it is clear from the certificates received by the Registrar-General that these important words are frequently omitted when they should have been inserted. In the second place, by the linking together of the fact and the date of death, a difficulty is created by reason of the fact that the source of information may not be the same in both cases. The practitioner might have seen the deceased after death and might thus feel justified in omitting the words "as I am informed"; but his personal knowledge need not have extended to the date of death as to which he might have been obliged to accept the statement of the relatives.

In the new form the two statements are separated and the opportunity is given to the certifying practitioner of indicating very simply whether he certifies from his own knowledge or merely reports the statement made to him by striking out one of the alternatives in each pair.

In the old form there were four instances in which the print had to be adapted so as to suit the sex of the deceased (his, her; him, her; he, she). These have been reduced to one; while the removal of the requirement as to the insertion of words and the general straightforwardness of the new form should, it is thought, make it distinctly easier for the certifying practitioner to complete. By the courtesy of the Registrar-General we print on the opposite page the exact text of the new form of certificate, underneath the old form in order to facilitate a comparison.

The remaining small supplies of the old forms in the hands of registrars or of medical practitioners are, we understand, not being withdrawn, so that the new form of certificate will only come into general use as the residual supplies are exhausted.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

(Continued from p. 516.)

SECTION OF MEDICAL SOCIOLOGY.

FRIDAY, JULY 25TH.

Has the National Health Insurance Justified its Existence?

THE whole of two sessions, morning and afternoon, were given up to the consideration of the answer to this question and the speakers approached the matter from every point of view. The President, Dr. **ARTHUR MANKNELL** (Bradford), introduced the subject by a judicial summary of the various headings involved in a complete answer of the question, without expressing his own opinion.

Representative Opinions.

Sir W. S. **GLYN-JONES** spoke for the insurance committees. He considered that the system had justified itself, but was far from fulfilling the promises made for it in Parliament when it was established. Whilst to the individual the goods had been delivered, the State was still waiting to receive what it had paid for. The preventive features of the Act had been a dead letter, and the National Health Insurance system would not be fully justified until all taking part in it coördinated their efforts in tackling what Sir George Newman described as "perhaps the main part of the health problem of the nation." You could not convert a grudging or incompetent doctor into a keen, tactful, competent practitioner by means of regulations. Too much importance had been attached to paper controls. His recipe would be to provide such conditions of, and remuneration for, medical treatment as would result in practitioners being as anxious to secure and to retain insurance patients as they were to secure and retain private patients. If, in addition, the insured person were educated to recognise efficient treatment, then with the free choice of doctor the rest could be left to the ordinary laws of supply and demand. Now that the profession and the Government were to have a rest from bartering there was some hope that both would take "a long view" and soon be engaged in administering a service of which both would be proud.

Alderman **FRANCIS ASKEW**, J.P. (Hull), spoke for the approved societies. In 1911 the voluntary members of friendly societies numbered 5,000,000. The Act brought into compulsory insurance 15,000,000 persons. The actuarial advice tendered to the authors of the Act had worked out fairly well, including the experiment dealing with the introduction of women workers. Imperfect as the Act and its administration might be in some respects, the insured population would never vote for its repeal.

Mr. **TOM HARLAND** (Bradford), speaking for male insured persons, thought the time would come when dental and optical treatment, convalescent home, and hospital treatment would be definite supplementary benefits for everyone insured. Some societies already gave these benefits. Some doctors gave of their very best in skill and attention, but some gave it rather grudgingly as if they were not well enough paid. He thought the funds of the societies suffered from careless certification. Furthermore, doctors with overcrowded panels should get more assistance in order to avoid long waiting queues. He suggested that all insured persons should be medically examined, say, every five years. [A similar suggestion was made by Dr. Peter Macdonald two days before.] Most insured persons did not visit their doctor early enough.

Miss **FLORENCE GODFREY** (Birstall), speaking for female insured persons, was glad to think that the majority of insured women, of whom all sorts of terrible things were predicted, did the right thing and only applied for benefit when it was needed. The Act needed amending as regards married women and pregnancy. Some women got doctors' certificates and received sick pay during the whole of pregnancy, although doing their household work, while others received nothing but their maternity benefit. Many women were not satisfied with the panel system and said they did not receive as good treatment as did private patients. The complaint was sometimes made that it took the doctor only as many minutes as there were panel patients to give them attention, and in such a case the most ignorant of them knew they were not receiving the treatment they had the right to expect. The regulations as to emergency calls were too stringent. The main special benefit of her society was convalescent benefit and it was of great value. She thought the Act had justified its existence, and, if rightly and sympathetically amended, would do so still more in the future.

Dr. A. E. **BARNES** (lecturer on medicine, University of Sheffield) said he could not speak for consultants as a class, but he had been intimately acquainted with the working of the Act since its conception. He considered that the Act had been one of the greatest advances in administrative medicine in our time. It had brought organisation into what had been chaos. It was a revolution which by means of evolution would eventually become the most important factor in public health. He considered that the panel committees had great opportunities, and in several instances they had shown their interest in research work. The service given by the panel practitioner had improved, and young men were going into the service with avidity. Three of the points for criticism were the prominence given to the bottle of medicine, the increase of neurotic illness, and the lack of a consultant service. He thought these matters could be dealt with by the substitution of a medical treatment fund for the present drug fund, so that the doctor who wished to have consultations, special appliances, or laboratory help could obtain them out of the fund by economising in the doling out of unnecessary medicines.

Dr. G. B. **HILLMAN** (Wakefield) voiced the views of the general practitioner. He enumerated the essentials of a satisfactory medical service. He thought the institution of panel committees had promoted a more cordial and brotherly feeling among practitioners. In his opinion the Act had led doctors to take a wider view of their duties in the direction of preventive medicine. The old pathetic belief in the bottle of medicine was slowly passing away, and more faith was arising in modern methods of examination and greater appreciation of the progressive practice of medicine. Amongst other instances of progressive action on the part of panel committees he mentioned the West Riding scheme for laboratory facilities and the establishment of a prize in clinical medicine at Leeds University.

Mr. H. S. **SOUTTAR** (surgeon, London Hospital), speaking on behalf of the voluntary hospitals, said there were misgivings when the Act came into force as to its possible effect on the income of the hospitals and the number of their patients. At the London hospitals they found that the number of out-patients had diminished. Practically speaking, out-patients were only seen on a letter from the panel practitioner to whom an answer was sent in due course. The figures showed that the hospital was not being swamped by patients who ought to be treated by their panel doctor, and that in the second place the serious cases sorted out by the panel practitioners were able to receive more careful attention. If in the future the scope of the Act was enlarged so as to extend its operation to dependents and to include hospital treatment among the benefits, hospitals would be still further relieved of minor cases and the consultative value of their services increased. Interchange of information between the consultant and the general practitioner would become a matter of routine; the early reference and admission of serious cases would be assured; and along these lines there would be developed a great health service strong in the fight against disease and in the interests of the country.

Mr. J. J. Barron (secretary-superintendent, Bradford Royal Infirmary), speaking for the administrative side of the voluntary hospitals, said that since the establishment of the Act at the Bradford Royal Infirmary there had been, as in the case of the London Hospital, a decline in the number of out-patients but a considerable increase in the number of in-patients. As the main items of hospital expenditure are incurred in the in-patient department, he thought the hospitals might fairly ask from the approved societies and the insurance committees the costs to which they were put in dealing with insured in-patients.

Dr. J. J. Buchan (M.O.H., Bradford) thought the National Health Insurance Act had justified its existence from the point of view of preventive medicine. Panel practitioners were now directly interested in the environment of their patients, and since the passing of the Act he had received more reports from medical practitioners with regard to bad environment. By the passing of the Act 16,000,000 people had been encouraged to regard illness in all its stages as worthy of consideration and to seek medical treatment at the onset, when it was more likely to be effective. Most insurance committees had done something in the direct education of the public in health matters. Special efforts had been made against certain diseases—e.g., tuberculosis. Lastly, medical benefit had been a great effort to ameliorate disease among the sufferers and to mitigate its after-effects. During the first ten years, owing to the encouragement of a greater care of the sick, there might be an apparent tendency towards increased sickness, but over a longer period we should find a marked decrease, and with this decrease a greater efficiency of each unit in industry.

Discussion.

Dr. Harold Beadles (West Ham), speaking as chairman of an insurance committee, said the scope of the Act must be widened by the inclusion of dependents and persons who at present came under the Poor-law. He would like to see the work put under committees of the county councils and county boroughs and the same benefits arranged for sickness, accidents, unemployment, old age, &c., all on a contributory basis. We spent £280,000,000 per annum at present on social schemes, and he did not think a comprehensive insurance scheme such as he had mentioned would increase the cost.

Dr. J. F. Walker (Southend-on-Sea) said there was still a suggestion of slight about the term "panel doctor." The medical service subcommittee was not quite satisfactory. He thought a panel medical court of honour would be more effective. The delay in granting sickness benefit frequently gave rise to criticism. It was often necessary to give a bottle of physic in order to get other advice acted upon.

Dr. Herbert Jones (M.O.H., Herefordshire) thought panel practitioners might call in the medical officer of health more than they did. He found it a great advantage himself to be on the panel committee for the county.

Dr. G. W. Skene (Willesden) said that general practitioners were not unanimous in supporting the panel system. The reason was not financial but arose from irritating features of administration. The whole of the profession ought to be brought in if possible.

Mr. W. Gill, J.P. (Manchester Unity of Oddfellows), said the approved societies as well as the doctors had to put up with administrative irritants. A medical service subcommittee composed of doctors would not answer. It must be two-sided. Insurance committees had lost the most interesting part of their work in tuberculosis. It would be a mistake and dehumanising to transfer the work of insurance committees to county and borough councils.

Dr. Peter Macdonald (chairman, York Insurance Committee) said medical men were dead against the Act in 1912, but now, in the words of Dr. Stancomb, "it would take a high explosive to blast them out of it." Speaking as a member of an insurance committee, he believed that the panel practitioners mostly did their work well. Contract work had given a value to preventive work by the general practitioner.

Dr. G. H. Sedgwick (Rotherham) said that if the Act were to justify itself it must be made complete. Every general practitioner must be got on to the panel and the invidious distinction between the "family" doctor and the "servants'" doctor done away with.

Dr. J. W. Bone (Luton) thought those who gave the service were as a rule satisfied. In some places like Bournemouth fees were too high to make panel practice worth while. He did not think insured persons were quite satisfied. The friendly societies' institutes did not have free choice of doctor. Insured persons did not like the double wait at the doctor's and the chemist's. The delay in giving sick pay also caused dissatisfaction. Some agents of friendly societies sometimes made difficulties in order to persuade persons to join their particular societies.

Dr. C. Buttar (London) said they should get rid of lay control. Medical benefit should be separated from sickness benefit and put under the Ministry of Health. Discipline should be entrusted to committees of the medical profession.

Mr. C. J. Bond (Leicester) said the Insurance Act was a great step forward. In contrast with the London Hospital and Bradford Infirmary out-patients at Leicester were now nearly pre-war in numbers. Fifty thousand patients were now waiting for beds in the county and an increased hospital service was greatly needed.

Dr. E. W. G. Masterman (medical superintendent, Camberwell Infirmary) said the London Poor-law hospitals treated more patients than the London voluntary hospitals and that 95 per cent. of their patients were sent in by panel practitioners. They had no waiting list and never refused a patient. The Poor-law hospitals must be linked up with the general medical service.

A Summing Up.

Dr. H. B. Brackenbury (London) endeavoured to sum up the discussion. He thought the figures for out-patients in Leicester were exceptional and that the figures for the London Hospital and Bradford Infirmary were the rule, indicating that panel practitioners were not shuffling off their patients on to the hospitals. Panel practitioners were evidently contributing to preventive medicine by drawing attention to environment when it was bad. The insurance system was agreed to have justified itself by all the speakers. It was an encouragement of thrift, and all the speakers included its extension in their programme. He agreed that medical benefit should become part of the enlarged health service of the country, and should be separated from the cash benefit. It was not clear why all general practitioners did not go on the panel. He did not think disciplinary control could be handed over to the doctors, although ideally it might be better to do so. Professional honour was a better guide than regulations. A great extension in the insured population was needed by the inclusion of 30 millions of dependents. He was not afraid of the profession becoming commercialised by the payment of the present honorary staff of hospitals. Insurance committees cannot deal with public health matters on behalf of a section of the population only, and when the insured population was extended the work of the insurance committees would need to be transferred, but their clerks and officials would still be required. Compulsory physical examination of insured persons at stated intervals could not be enforced, and he doubted if voluntary examination would be much use. He believed that loose and imperfect certification by panel practitioners was quite rare and that the difficulties of exact certification were not understood by the layman. In order to provide for thorough medical work with a due regard for the preventive aspect it might be a good plan to increase the capitation fee.

A FORECAST OF THE MOTOR SHOW.

Improvements in 1925 Models.

By J. Marshall, M.I.A.E.,
LONDON MANAGER OF MESSRS. MANN, EGERTON AND CO., LTD.; OFFICIAL CONSULTING ENGINEER, MEDICAL INSURANCE AGENCY.

The motor show opens at Olympia on Oct. 15th. Since the popularisation of motoring this annual exhibition of new models and accessories has become a function of importance to all classes of the public, and there is reason to anticipate an even larger attendance than last year. Certain innovations which have proved successful on a few 1924 cars have now been much more generally adopted; actual reductions in price are not to be looked for in many cases, but since certain accessories, formerly costly extras, are now included as standard equipment, the 1925 cars complete for the road will be a better proposition than were the 1924 models.

Outstanding Features.

Balloon tyres, four-wheel brakes, and cars completely equipped with accessories are likely to be the outstanding features of the show, and the advantages of their adoption are worth consideration.

Balloon tyres mean easy riding over rough roads, with consequent elimination of severe shocks on the chassis. If tyres have to be changed they are much easier to put on than the ordinary type, and certainly less laborious to pump. Side-slips are, to a certain extent, minimised. It is, of course, quite possible for cars fitted with ordinary type tyres to be converted to low pressure ones at a cost varying from £15 upwards, according to size. It is important to remember that the whole secret of the successful use of balloon tyres lies in maintaining the pressure exactly as specified by the tyre manufacturers, and for this purpose a simple and inexpensive gauge, of the type shown in Fig. 1, should be carried by every motorist for periodical testing.

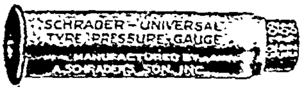

Fig. 1.—Tyre pressure gauge.

Four-wheel Brakes.—These will be standardised on many cars or can be fitted at an extra cost varying from £10 to £50. These brakes should be of great benefit to doctors whose journeys are confined largely to highly polished tarred roads or setts, where risks of skidding are great. With four-wheel brakes it is not easy to make a car side-slip, and when used for the first time a comfortable sense of security is experienced.

Accessories.—Such accessories as a petrol gauge, windscreen wiper, or driving mirror can be looked for as standard equipment on most cars.

Considerations of Price.

Reductions in prices of medium and higher p
cars can hardly be anticipated, principally b
these prices were more or less stabilised wh
McKenna duties were taken off on August 1st.
majority of makers of smaller or lower priced car
issued their new prices, and these show certain r
tions. There is a strong possibility of continenta
American prices being raised i the near future

before the show. This is quite unnecessary, since between now and October values in second-hand cars are unlikely to change.

Fashions in Bodies.

Owing to the great advance made during the past year in all-weather equipment for touring cars, the coach-built all-weather type of body is becoming less popular. This is hardly surprising, since the old type of coach-built all-weather body with wooden pillars is a constant source of trouble. Its liability to rattle and the expense of keeping in good condition has been much complained of. The "Gwynne" or "All Steel" type of cabriolet is likely to remain popular. It is considerably more expensive than a touring body, but it offers the advantages of an open touring car combined with those of a completely enclosed one with glass windows. In contrast with the coach-built type, there are no rattles, and its lasting qualities are good. The appearance of both types of cabriolet body is shown in Figs. 2 and 3. However, the types of car most likely to be in demand this year are: (*a*) the saloon with and without partition, and (*b*) the touring car with first-class all-weather equipment. If this equipment is made on up-to-date lines and by a good coach-builder it is practically wind and waterproof, and has the advantage of being put up and down in two or three minutes. Another type of car very

ny
io le
ns

and paintwork can be entirely dispensed with. It has been found quite durable, and in the event of an accident, easily renewable. To clean these bodies it is only necessary to sponge them over and dry off. Recently new developments of this idea have come to the front, one of which is termed the "Jazz" (see Fig. 4). The body is first covered with fabric and this is afterwards treated with coats of celluloid and varnish, the result being a durable and unusual finish not easily scratched. Fabric can be used with intricate or elaborate patterns in colour, according to the taste of the owner. The new process is slightly less costly than good paintwork and does not crack or blister. Bodies which have been treated in this way and have been on the road for nearly a year show small signs of wear.

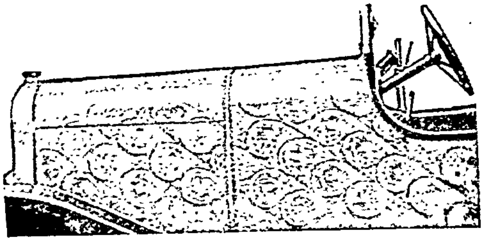

FIG. 4.—A "jazz" finish celluloid and varnish over fabric.

How to Look at the Show.

As a result of many years' experience of the shows I have come to the conclusion that it is quite futile for one with a "will to purchase," and not much time to spare, to go to the show with the idea of looking round generally and coming to some decision. He may study many different makes, and each one as he goes on seems to present something better than those he has previously seen, until at the end of one or two days he is hopelessly befogged. It is much better to study quietly the makers' descriptions of a few cars in which he may be interested, and go with the object of seeing these and decide on their respective merits. If he is not a really experienced motorist, it is advisable to consult an independent expert before coming to a decision. Of course, if he wishes just to nose round the show as if he were at a horse show he can spend a very joyous day doing so. Even if he obviously does not mean business, the many questions which occur to him during his perambulations are usually answered with extreme courtesy by the salesmen on the various stands. But should some lack of interest be apparent at busy times, it must not be forgotten that the questions of would-be purchasers are likely to lead to more business than desultory inquiries from men generally interested in motor-cars, and some toleration should be shown. One of the most important points the would-be purchaser should keep in mind is that because a car is cheap in price it is not necessarily made of inferior quality material, and the workmanship embodied need not be inferior to that on higher priced cars. It should be remembered that at the present day the small low-priced car is produced in large numbers in works equipped with modern labour-saving machinery. The greater the output the better the finished article is true in many cases, since material must be purchased in huge quantities and the very best type of up-to-date automatic machinery must be used. I always find, however, when advising doctors as to the purchase of any car, that so many personal and professional factors have to be taken into account that it is almost impossible to generalise and each case has to be considered separately.

The show arrangements are on much the same lines as last year—the main hall and coach-building annexe, the new annexe, where cars as well as accessories will be shown, and the usual two public entrances, i.e., Hammersmith-road and Addison-road. There is ample space for the parking of private cars in neighbouring streets, such as Blythe-road and Russell-road, and cars can be left there with safety.

DIABETIC COMA IN INSULIN-TREATED DIABETES.

To the Editor of THE LANCET.

SIR,—Much has been published during the last 12 months on the technique of insulin treatment in diabetes. I have, however, seen very few records of cases of coma treated with insulin, although these cases present very special difficulties both of diagnosis and treatment. On the one hand, intercurrent infection is probably the commonest precipitating cause of coma—more especially in patients already on insulin, and the detection of the source of infection in coma may be exceedingly difficult. On the other hand, there is no time in coma for the graduated administration of insulin, and even with blood-sugar estimations it is not an easy matter to gauge the amount of insulin required. Moreover, it is probably not generally recognised what very large doses of insulin may be needed in this condition.

The following cases illustrate both the difficulties referred to above:—

CASE 1.—A girl, now 9 years old, had suffered from a severe type of diabetes for 18 months before commencing insulin. This had been started in May, 1923, when she was almost moribund; and after a long period of observation in hospital she had been discharged on a diet of 900 calories and a dose of 30 units of insulin daily, given in two injections before the morning and evening meals. Except for an attack of broncho-penumonia in January, 1924, she had remained in good health ever since, had fully regained her weight, and was attending school. Her blood-sugar had been estimated at fortnightly intervals during the year and had nearly always been below 0·17 per cent. in the afternoon. She attended the hospital on April 24th last for this purpose, when her blood-sugar was 0·11 per cent. at 4 P.M. The following day she complained of headache, her temperature rose to 102° F., and she refused to take any food. Her mother therefore discontinued the insulin, since she was fully alive to the danger of hypoglycæmia, and thought that the insulin must be stopped if no food was taken. The temperature remained high on the 26th, and she began to vomit in the evening. When seen on the morning of the 27th the vomiting had become almost constant, but there was no pain in the stomach. There was marked hyperpnœa, with an expiratory grunt suggesting pneumonia and the alæ nasi were working. At the right base there was a very definite pleuritic rub. The breath smelt strongly of acetone and the urine contained large amounts of sugar and acetone. She was ordered 60 units of insulin in the day. At 6.30 P.M. she was drowsy and still vomiting. The temperature was normal. The blood-sugar was 0·47 per cent. When seen by her doctor (Dr. C. McCay) at 10 P.M. she had just become unconscious. She was given another 20 units of insulin, making 80 units since 9 A.M., and brought by car to the hospital. On arrival at the hospital she had regained consciousness; her blood-sugar then was 0·4 per cent. A further 60 units of insulin during the night reduced her blood-sugar to 0·11 at 9.30 the following morning. Thereafter she received 40–50 units insulin daily. On examination on the morning after admission her breathing was natural and no abnormal physical signs could be found in the chest; the pleuritic rub had entirely disappeared. She was still drowsy, however, and her mental condition was very peculiar. On the following day (29th) she showed signs, for the first time, of a commencing facial erysipelas, and with its appearance the mental condition became normal. The erysipelas ran a normal course of five to six days' duration, with a high temperature and with one short relapse; but it was only possible gradually to reduce the insulin, some time after the temperature had fallen to normal, from 40–50 to 35 units daily. She is now (August, 1924) quite well again, except for the fact that she requires about 8 units more insulin daily to keep her blood-sugar within normal limits on the same diet as before.

This child therefore required 140 units of insulin in 24 hours to restore her blood-sugar to a normal figure; and the acidosis apparently persisted for some time after the blood-sugar had reached a more or less normal figure. When first seen, her condition

A FORECAST OF THE MOTOR SHOW.

Improvements in 1925 Models.

By J. Marshall, M.I.A.E.,
LONDON MANAGER OF MESSRS. MANN, EGERTON AND CO., LTD.; OFFICIAL CONSULTING ENGINEER, MEDICAL INSURANCE AGENCY.

The motor show opens at Olympia on Oct. 15th. Since the popularisation of motoring this annual exhibition of new models and accessories has become a function of importance to all classes of the public, and there is reason to anticipate an even larger attendance than last year. Certain innovations which have proved successful on a few 1924 cars have now been much more generally adopted; actual reductions in price are not to be looked for in many cases, but since certain accessories, formerly costly extras, are now included as standard equipment, the 1925 cars complete for the road will be a better proposition than were the 1924 models.

Outstanding Features.

Balloon tyres, four-wheel brakes, and cars completely equipped with accessories are likely to be the outstanding features of the show, and the advantages of their adoption are worth consideration.

Balloon tyres mean easy riding over rough roads, with consequent elimination of severe shocks on the chassis. If tyres have to be changed they are much easier to put on than the ordinary type, and certainly less laborious to pump. Side-slips are, to a certain extent, minimised. It is, of course, quite possible for cars fitted with ordinary type tyres to be converted to low pressure ones at a cost varying from £15 upwards, according to size. It is important to remember that the whole secret of the successful use of balloon tyres lies in maintaining the pressure exactly as specified by the tyre manufacturers, and for this purpose a simple and inexpensive gauge, of the type shown in Fig. 1, should be carried by every motorist for periodical testing.

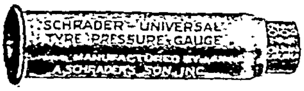

Fig. 1.—Tyre pressure gauge.

Four-wheel Brakes.—These will be standardised on many cars or can be fitted at an extra cost varying from £10 to £50. These brakes should be of great benefit to doctors whose journeys are confined largely to highly polished tarred roads or setts, where risks of skidding are great. With four-wheel brakes it is not easy to make a car side-slip, and when used for the first time a comfortable sense of security is experienced.

Accessories.—Such accessories as a petrol gauge, windscreen wiper, or driving mirror can be looked for as standard equipment on most cars.

Considerations of Price.

Reductions in prices of medium and higher priced cars can hardly be anticipated, principally because these prices were more or less stabilised when the McKenna duties were taken off on August 1st. The majority of makers of smaller or lower priced cars have issued their new prices, and these show certain reductions. There is a strong possibility of continental and American prices being raised in the near future: in fact, one or two American makers have already decided on this step.

The broad question as to whether to buy an expensive car designed to last some years, or an inexpensive one to be replaced after, say, two years, is a point that can only be decided in relation to a doctor's special circumstances. Obviously, in a better-class practice it is desirable to run a better-class car, which cannot economically be disposed of until it has given five to eight years' use. In no case is it wise to contemplate exchanging a car until it has run approximately 15,000 miles. We are frequently asked whether, when the purchase of a new model being contemplated, negotiations as to the disposal or exchange of a second-hand car should be hurried on before the show. This is quite unnecessary, since between now and October values in second-hand cars are unlikely to change.

Fashions in Bodies.

Owing to the great advance made during the past year in all-weather equipment for touring cars, the coach-built all-weather type of body is becoming less popular. This is hardly surprising, since the old type of coach-built all-weather body with wooden pillars is a constant source of trouble. Its liability to rattle and the expense of keeping in good condition has been much complained of. The "Gwynne" or "All Steel" type of cabriolet is likely to remain popular. It is considerably more expensive than a touring body, but it offers the advantages of an open touring car combined with those of a completely enclosed one with glass windows. In contrast with the coach-built type, there are no rattles, and its lasting qualities are good. The appearance of both types of cabriolet body is shown in Figs. 2 and 3. However, the types of car most likely to be in demand this year are: (*a*) the saloon with and without partition, and (*b*) the touring car with first-class all-weather equipment. If this equipment is made on up-to-date lines and by a good coach-builder it is practically wind and waterproof, and has the advantage of being put up and down in two or three minutes. Another type of car very useful for professional purposes only is the two-seater coupé with dickey.

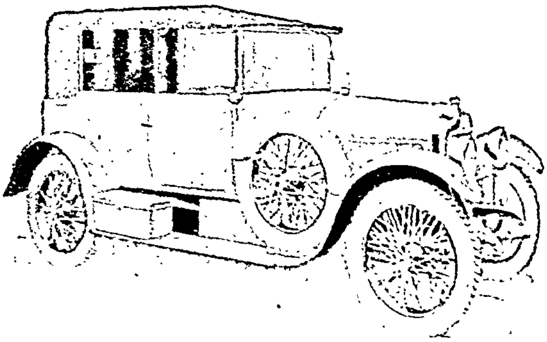

Fig. 2.—A cabriolet with a "Gwynne" head.

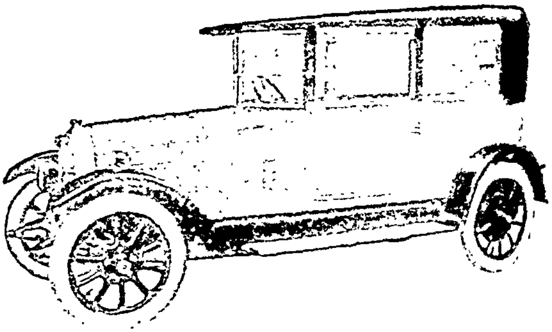

Fig. 3.—A cabriolet with a coach-built head.

The so-called "Chummy" (or "occasional four-seater") bodies seem to be less popular, since the rear seats of this type of body are extremely uncomfortable, and the two-seater with dickey is returning to favour. Although the occupants of the back seat are not under cover, this disadvantage is more than counterbalanced by the extra comfort obtained when it is not raining.

New Fabrics for Body Work.

Many small or medium powered cars will have bodies panelled with fabric leather in place of metal or plywood panels. This type is commonly called the "Weymann," after its original inventor. It has many advantages over the ordinary body, in that it can be made very light, has no creaking joints or drumming.

may be claimed for it of counterbalancing a purely calorimetric standard of food values. a safeguard of diminished importance since the discovery of vitamins. It seems, indeed. not impossible that the belief may rest upon an empirical knowledge of the value of fresh food and. if this be so. it might be compared to a rough paraphrase of the theory of vitamins in terms of magic and the very form of the word "vitamin" may have reinforced the popular idea that life is inherent in food. making the new discovery all the more readily acceptable as the scientific confirmation of a vague or unconscious belief. It is interesting as an example of the development along different lines of an idea that is possibly rational at bottom to compare the neurotic fantasies of the patient with the prescription of Paracelsus for manufacturing an "homunculus" by the magical "digestion" of bread and wine, and these end-results with the religious aspect of the idea in the Laws of Manu, which instruct the pure Brahmin to worship the food that he eats "because food is the life."

Some emphasis has been laid on the general character and prevalence of the patient's idea that life is inherent in food because it seems likely that it plays a part in many minor antipathies. such as would commonly be regarded as meaningless eccentricities or imputed to a delicate digestion, yet might prove explicable and susceptible of correction. One slight example may be given in the case of a young married woman, in no way neurotic, who had a horror of biting into any fruit, such as gooseberries, grapes, or stewed cherries, whose contents were semi-liquid. The feeling was carried back to childhood and the memory of stepping on gooseberries lying under the bushes, then to stepping on an egg, and the repugnance was found to be due to the idea that she was "destroying life."

I am, Sir, yours faithfully,

F. A. HAMPTON.

Queen Anne-street, Cavendish-square, W., Sept. 2nd, 1924.

AMMONIA AND CHLORINE IN THE DISINFECTION OF WATER.

To the Editor of THE LANCET.

SIR,—I have noted with interest the annotation in your issue of August 23rd on the effect of ammonia on the chlorination of water as reported by Major C. H. H. Harold and Captain A. R. Ward, and since then I have had an opportunity of reading the original article as published in the *Journal of the Royal Army Medical Corps*. As I was responsible for the introduction of the chloramine process for water purification, perhaps I might be permitted to make a few remarks on the results obtained. After I had confirmed Rideal's observation that ammonia increases the germicidal effect of bleach solutions,[1] the details necessary for the successful application of the process on a large scale were worked out,[2] and it was adopted by Ottawa, Canada, for the treatment of the whole supply of 20 mill. imp. galls. per diem. It has also been used successfully at Denver, Colo., for the prevention of aftergrowths, and I believe that it has been used by Diénert in Paris.

When the process was still in the experimental stage I realised that a combination of chlorine gas and ammonia would be an almost ideal combination in many respects, but laboratory experiments showed that the tendency was for the formation of ammonium chloride which has no germicidal value. The research department of Messrs. Wallace and Tiernan, New York, studied this combination, and it was tried out in Ottawa in 1919. The results, however, were so inferior that it was decided to revert to the former mixture of bleach and ammonia. I also used ammonia and bleach in experimental work in the Vladivostock area in 1918, but owing to the possibility that *E. histolytica* might be present, it was not considered advisable to use this process for the sterilisation of the water-supply of the troops as there is no experimental evidence as to the effect of chlorine compounds on these organisms.

The disparity between my results and those of Harold and Ward might be due to the use of autoclaved water by the latter, whilst I used untreated fresh water containing a relatively large amount of colour (80 p.p.m. Pt-Co scale). The treatment of a natural water by heat under increased pressure would result in a definite increase in the pH due to the loss of free and half bound carbonic acid. The resulting slight alkalinity would produce some hypochlorite on the addition of chlorine gas, or its aqueous solution, and the conditions would then be favourable for the formation of chloramine. The same condition would also retard the velocity of the action of the bleach solutions.

Before any scheme involving a combination of ammonia and chlorine gas is tried out in the field I would suggest that experiments should be made with waters at their natural pH and also that the conditions, found by practice on a large scale to be the most favourable for bleach and ammonia, should be tried out. In my opinion the chloramine process is essentially one most suitable for small doses and long contact periods. Short contact periods are often essential in military work, and in this case it would appear desirable to follow the suggestion of Sir Alexander Houston (Reports to Metropolitan Water Board) of using super-chlorination followed by de-chlorination. This process was used to some extent during the war, but its possibilities do not appear to have been developed to the full extent.

I am, Sir, yours faithfully,

JOSEPH RACE.

Devonshire Hospital, Buxton, Sept. 2nd, 1924.

ANTHELMINTICS.

To the Editor of THE LANCET.

SIR,—On reading the very interesting leading article on anthelmintics in your issue of July 19th it occurs to me that a little more might be added in the presentation of this subject. For one thing, your surmise that the error in the work of Hall and Hamilton on the anthelmintic constituents of chenopodium was due to distillation at insufficiently low pressure is apparently correct. This is the conclusion recently arrived at by my colleague, Mr. Hamilton, after a conference on this subject with Dr. Nelson of the Bureau of Chemistry of the United States Department of Agriculture, and a comparison of the work with that of Dr. Nelson.

As regards carbon tetrachloride, the question of safety brings to light a somewhat unusual condition. Carbon tetrachloride appears to be a drug which has no minimum lethal dose. It has been given in hundreds of thousands of human cases—over a hundred thousand in Fiji alone—and has been given to scores of dogs experimentally and to many thousand in veterinary practice. Ordinarily dogs will tolerate enormous doses, up to 25 c.cm. per kilo (or 83 times the therapeutic dose of 0·3 c.cm. per kilo of 100 per cent. effective action against hook-worms), without evident bad results. Human patients have taken as much as 50 c.cm. in the course of a few consecutive days. Deaths among human beings and among dogs and fur foxes have in almost all cases followed the administration of a therapeutic dose. On the other hand, chenopodium has a safety factor of only five on the basis of the therapeutic dose for removing ascarids from dogs (0·1 c.cm. per kilo) as compared with the minimum lethal dose of 0·5 c.cm. per kilo, or a safety factor of only 2·5 on the basis of a moderately effective (much less than 100 per cent. effective) dose for removing hook-worms from dogs (0·2 c.cm. per kilo) as compared with the minimum lethal dose.

The extreme tolerance of dogs and man for carbon tetrachloride in the great majority of cases suggests was strongly suggestive of a commencing pneumonia. The erysipelas did not manifest itself until four days after the commencement of her illness, and its relation to the initial symptoms remains doubtful.

CASE 2.—A married woman of 35 was seen on two occasions in January, 1924, in consultation with Dr. D. B. Spence, to whom I am indebted for the records. As the patient lived many miles away it was impossible to carry out regular blood-sugar estimations. This patient had had diabetes for between one and two years before commencing insulin in April, 1923, under the care of a London consultant. She was stated actually to have been in coma when insulin was started. For nine months she had been on a fairly strict diet, with 20 units of insulin daily. She had gained half a stone in weight, and had apparently been passing sugar at intervals during this period. For several weeks before I saw her she had been feeling depressed, and for six days had suffered from obstinate constipation. Five days previously she was said to have "caught a chill," but had not been seen by her doctor until the previous day, when insulin had been stopped for 24 hours, and she was already on the verge of coma, with drowsiness, deep breathing, and marked polyuria and glycosuria. When examined at midday on the 27th, although she had had 40 units of insulin since the previous evening, she was already in coma. The temperature was below 96° F., with a feeble pulse and marked hyperpnœa. At both bases there was a very well marked friction rub. The abdomen was distended and resistant; the bowels had been opened with an enema on the previous day for the first time for three days. The blood-sugar was 0·46 per cent., and the ferric chloride test for diacetic acid in the urine was strongly positive. She was given 140 units of insulin during the next 18 hours. This had the effect of bringing her out of coma. But on the 28th there was some sweating, she again became semiconscious, and there was very little secretion of urine containing no sugar. She was therefore judged to be hypoglycæmic, and the administration of insulin slowed down. On the morning of the 29th the breathing had again become deeper, and there was slight glycosuria; she was given 40 units of insulin during the day.

When I saw her for the second time on the afternoon of the 30th she was completely comatose, although she had received 140 units of insulin since 1 A.M. A catheter specimen of urine showed a trace of sugar and a well-marked ferric chloride reaction. The blood-sugar was 0·16 per cent. For the past three days the temperature had varied between 98° and 100°, and the pulse between 90 and 120. There was now consolidation of the right lower lobe and friction at the left base. From this time on she became progressively worse. Insulin was discontinued the same evening, and she died in the early morning of Feb. 1st, with a terminal pyrexia of 105°. During her illness she had on an average two pints of fluids daily by the mouth and numerous rectal salines; and during the four days of intensive insulin treatment she received 400 units of insulin. Almost at the end of this period her blood-sugar was 0·16 per cent.

It may be urged that no patient on insulin should ever be in danger of coma. But insulin is now in very general use, and a large number of patients become so habituated to it that they tend to lose contact with their doctor. When it is realised how swift may be the onset of coma, especially having regard to the very large amount of fat in the average diet of the patient on insulin, it is not altogether surprising that such accidents should happen from time to time.—I am, Sir, yours faithfully,

W. T. COLLIER, *M.C.*, M.D. Oxf.,
M.R.C.P. Lond.

Oxford, August 26th, 1924.

DYSPEPSIA OF MENTAL ORIGIN.

To the Editor of THE LANCET.

SIR,—The neurotic patient is so commonly eccentric and fastidious in diet that it seems natural to accept the attitude as inevitable to the peculiar temperament of the patient, but the following extreme example, though it does not bring to light any new ætiological factors, seems worth recording, since it shows that, in some cases at least, the apparent waywardness may be the result of a logical train of thought of a kind not peculiar to morbid psychology.

The patient, an unmarried woman of 35, had suffered for some 15 years from a feeling of distension, nausea, and palpitation of the heart occurring immediately after meals. The symptoms were apparently those of an organic dyspepsia, but on close questioning it was found that they were only evoked by certain articles of food which at first sight seemed to have nothing in common. Any food that was coloured red, especially tomato soup or red gravy, salads, raw fruit, all root vegetables, eggs, and, in general, any food that was uncooked or underdone brought on the symptoms. The symptoms also occurred if she were breathed upon by a man, so that a visit to the dentist was invariably followed by a sharp attack.
